The subjects were young calves, numbers I. and II., weighing respectively 3 cwt. 40 lbs., and 4 cwt. 70 lbs. One ounce of seeds was eaten with bran by calf No. I., and caused no rise of temperature, no malaise, or loss of appetite, but pale fluid and foetid diarrhoea, which passed off in three days. When offered further quantities of seeds mixed in ordinary food this animal, like all our others, absolutely refused to eat them. The later doses were given either as drenches or in ball.

Three ounces of seeds caused the same phenomena as the first dose of one ounce.

We then gave successively 4½ and 6 ounces of defatted seeds. These doses did not elevate the temperature to any noticeable extent, and caused the faeces to become hard and dark, becoming normal in two or three days. Otherwise no abnormality was observed.

Thinking that possibly our subject had acquired a measure of immunity, we then offered calf No. II. 12½ ounces of whole seeds mixed with bran, which he ate, and four days later 18 ounces of pressed seeds in ball. The highest temperature noted was 102° 8' F., and for the rest the whole seeds caused diarrhoea, whilst the pressed seeds tended to make the faeces hard and dark.

Serum was taken from each calf after the observations were ended and tested for anti-ricine by the precipitin test with ricine. No positive evidence of anti-ricine was obtained.

We turned our attention in the next instance to seeds of two varieties cultivated as ornamental plants, viz., *R. sanguineus* and *R. Zanzibariensis*.

We gave single large doses of each of them to two fresh calves of about the same weight, namely, 2½ to 3 cwt.

Calf III. had 14 ounces of *R. sanguineus*, and calf IV. had 16 ounces of *R. Zanzibariensis* in ball.

Calf III. died in eight days, and calf IV. in 3½ days.

R. sanguineus. On the morning of the first day after dosing calf III. was weak, temperature 106.5°, turbid serous lachrymation from both eyes, and mucus about the size of a barley grain under each eye, mucous discharge from nostrils, fluid diarrhoea, straining, but not passing much.

Second day: Temperature 104°, mucous discharge at nostrils, stertorous breathing, watery diarrhoea.

Third day: Temperature 104°, very marked stertorous breathing, watery discharge from eyes, and mucous discharge from nose, pulse feeble. Food and drink were refused, although the animal was not very dejected in appearance, and was still able to walk fairly easily.

Fourth day: The symptoms were much the same, but the breathing was easier.

Fifth day: Temperature 102° 8', marked stertor with each inspiration, which was very deep, strings of mucus hanging from nose and mouth, lungs apparently normal, pulse fast and weak, emaciated, abdomen tucked up and back arched, but still standing, semi-solid faeces passed continually.

Sixth day: Seemed to be improved, temperature 103° 7', breathing almost quiet, pulse 108 (weak), still tucked up and back arched, straining but passing no faeces. The animal began to pick up hay and to drink. Later on the same morning distressing symptoms of coughing, with discharge of greenish stringy matter from the nose ensued, but at night there was no discharge and few coughing fits.

Seventh day: Temperature 103° 2', pulse almost imperceptible, 108 and weak, standing with head and neck outstretched and haggard look, deep gurgling cough with greenish, frothy, mucous discharge from nose and mouth, attempted defecation, but intestines empty.

Eighth day: Found dead.

The post-mortem examination which was made at once showed no gross abnormality; the lungs, heart, liver, kidneys, and spleen being normal. The four stomachs were full of food (hay). The fourth stomach showed at the pyloric end some congestion, being bright red gradually fading. The congestion extended for about two feet into the duodenum and ileum. No evidence of inflammation could be seen in any other part of the alimentary tract, and the intestinal contents were normal. The trachea and bronchi were full of froth.

R. Zanzibariensis. Calf IV. was dosed in the morning. At 8.30 p.m. of the same day temperature 101° 4'

lying down, outstretched, and marked tympanites; got up but showed no distressing symptoms, pulse fast and almost imperceptible, breathing fairly regular, watery discharge from both eyes, marked diarrhoea.

The subsequent daily temperatures were 98.8, 99.4, and 101.6°.

On the third day after dosage we asked Professor Reynolds to be so kind as to examine the calf as an independent outside observer, and he reported as follows:—Temperature 101.6°, pulse imperceptible at jaw, tail, or fetlock. Very dull, dejected, head held on ground, emaciated, tucked up abdomen, champing of jaws, extremities cold, no abnormality of pupil of eye, marked fibrillary muscular twitching chiefly on shoulder and thigh; no special amount of scouring. *Prognosis* most unfavourable.

The animal died on the same afternoon.

The only abnormality observed on post-mortem was a rose-pink to dark red congestion, probably in excess of the static congestion, of the latter half of the intestinal mucous membrane, the contents of intestine and caecum being viscid and yellowish red.

No fragments of husk could be seen in the ingesta. An attempt was made to recover ricine from the omasum contents by extraction with glycerine, but tests of the extract with anti-ricine serum were negative.

Our observations clearly show that the irritant effects of castor seeds are trifling in comparison with the general toxic effect.

The differences which we have observed in the effects of the various seeds with which we experimented are very puzzling. All the seeds contained ricine, as shown by the agglutination and precipitin tests. These tests are so delicate that they do not ordinarily serve to estimate the relative proportions. When occasion permits we intend to quantitatively compare the ricine content of the varieties in question. The small seeds contain a larger proportion of husk, which naturally tends to increase the dose, but this explanation is inadequate, for we gave equal or larger doses allowing for this factor, and moreover several times used defatted seeds in which the toxine is in greater concentration.

Our experiments at any rate tend to prove that the small variety is less toxic than the larger. I am informed that the small seeds are preferred for oil pressing, as giving an oil less liable to be drastic than that derived from larger sorts. It will be interesting to quantitatively standardise our specimens, as if it is found that the small variety has a lesser ricine content, that would explain the milder character of the oil. I believe the purgative effects of the oil to be due to the presence of infinitesimal traces of ricine. This opinion is supported by a recent statement made to me, but still requiring verification, that steaming the oil deprives it of purgative effect. This it would do by destroying any ricine possibly present.

DETECTION OF RICINE.

The protein-like toxins and ferments do not possess characteristic chemical reactions. The only chance of certainly identifying them is by means of their specific physiological effects. Of course, if a cake or mixture contains whole seeds, there is no difficulty. If husks are seen the case is suspicious, but the husks are not poisonous, and it is therefore necessary to find and identify fragments of endosperm, and further also to show that the ricine has not been destroyed, *e.g.*, by steam heating.

The agglutination test. Besides the toxophore ricine also possesses an agglutinophore group. Ricine extracts agglutinate blood corpuscles more or less rapidly according to purity and concentration. With pure ricine extracts and washed corpuscles the agglutination is shown in a dilution of 1:600,000. The agglutination is not dependent on the hæmoglobin for it is shown also by the

stroma or "ghosts." If blood corpuscles are disintegrated by distilled water, centrifuged, and suspended in saline, ricine extracts agglutinate the turbid suspension of "ghosts." Unfortunately the agglutination is inhibited by the presence of much protein. Nevertheless it is possible to observe it in 10 per cent. defatted castor seed to 90 per cent. linseed meal mixture. It is merely sufficient to extract at the incubator temperature with saline, and add the filtered extract to the blood corpuscle suspension. By grinding a fragment of pure castor seed for a few moments with saline and filtering, intense agglutination can be rapidly obtained with this extract.

In my experience the agglutinative power of croton and jatropa is greatly inferior.

The precipitin test. Not the least interesting property of ricine is the production of immunity. Beginning with dosage in very small quantities by the mouth, and proceeding to increasing injections, Erlich showed that in about four months a 4 to 8 hundredfold immunity can be produced. The case is specially interesting as the earliest investigation on immunity by Ehrlich. In general ricine immunity and anti-ricine serum show close parallelism to anti-diphtherine and anti-tetanus.

Anti-ricine serum gives a specific precipitin reaction with ricine extracts. It does not react with croton, and is absolutely diagnostic. Anti-ricine serum is now made by Merck, of Darmstadt, and is purchasable. It should be as fresh as possible, should be kept in the dark in the ice chest, and should be filtered before use. When a 1:50,000 solution of ricine in normal saline solution is caused to form a layer in a test tube, on an equal bulk of serum, a sharp zone of precipitate is found at the area of junction of the liquids within ten minutes, and a 1:70,000 extract causes a distinct reaction in 20 minutes. The German authorities (Miessner, Mooser, Kranich; (see Kranich, *Zeitschrift für Veterinärkunde*, 1912, 455) extract 2 grams of the ricine containing material with glycerine (40 c.c.) at 50° C., filter, precipitate with 350 c.c. of a mixture of equal parts of alcohol and ether, collect and air dry the precipitate, and extract it with 10 per cent. saline.

I have found that direct extraction during 12 hours with physiological saline (0.9 per cent.) is satisfactory down to at least 1 per cent. of defatted castor to 99 per cent. linseed meal. In performing the test one should make parallel blank tests (a) with linseed, or other meal extract, and (b) with the ricine extract and a normal serum.

DISCUSSION.

Mr. G. UPTON opened the discussion, pointing to the various influences which tended to the production of cheaper, and therefore inferior foods by means of adulteration. This was particularly the case with horse mixture. He would go so far as to say that in the big factories, where crushing was done, not a husk was discarded. With regard to the poisoning by beans or seeds (cascara, castor, etc.), this arose from the cakes which were sent over for consumption by animals. A law case was at present pending on the subject. The sender of the seeds disclaimed responsibility. Sometimes, in the hold of ship, cake bags and bags having poisonous seeds, such as croton or castor oil seeds, were broken loose, but the whole contents, were sent to the mill to be crushed, and trouble ensued. The chemists invariably urged that they were not liable; that they bought the cake in bags, and delivered it in bags, and had no responsibility for the contents. The speaker then narrated a case in which he had been sent for to deal with a large number of cows which were dying. The owner explained that they had been feeding on cake, of the quality of which he was himself suspicious, as the bags had been broken to pieces, and he could not be certain as to what they contained. The cows had been fed at

3 o'clock, and the speaker arrived at about 9 o'clock. He found the cows throwing off large quantities of blood by way of the bowels, and enquiry elicited the fact that they had had nothing else to eat but the cake. The conjecture that castor beans produced hæmorrhage and diarrhœa was supported by medical evidence and statements found in books. One of the cows had died, as he had been unable to keep her from straining. Her temperature was high, and the breathing such that he suspected pleurisy. On the Sunday the cow died, and, upon opening her, he found that every part of the bowels, every vein was engorged with blood, and the peritoneum full of blood serum; the pleura and pericardium were covered in the same way. He had known of several of these cases, and sometimes the milk contained blood.

Mr. R. BENNETT desired to know whether Mr. Upton had examined the blood in the fatal case he had mentioned, and whether he had satisfied himself that it was not a case of anthrax. Some cross discussion took place, and it appeared that Mr. Upton had not made any examination of the blood itself.

Mr. J. B. BUXTON referred to the question of immunity. Dr. Lander has remarked that it took some length of time to produce an anti-ricine. The speaker suggested that if a start was at once made with a mixture of toxin and anti-toxin, or ricine or anti-ricine, the period required for immunisation would be much curtailed. He had been struck by the lack of symptoms which had been shown as a whole by the animals with which Dr. Lander had experimented. There did not appear to be so much alimentary disturbance when the animal was poisoned by ricine per os as when the toxin was administered by subcutaneous injection. Subcutaneous injection, according to the speaker's experience, produced greater intestinal trouble characterised by blood extravasations in the intestinal wall, marked enteritis, enlargement of the spleen, and enlargement of the mesenteric lymphatic glands, accompanied by hæmorrhages in the gland substance. He suggested that the acute enteritis referred to by Mr. Upton was probably due to the husk as much as the seed, and apparently the husk did not contain ricine. With regard to the precipitation reaction, he would ask Dr. Lander whether he had ever compared the serum of animals that had been poisoned by mouth with those poisoned by subcutaneous injection, and, if so, whether he found any variation; whether a better precipitation was obtained in the case of an animal poisoned by subcutaneous injection of ricine than in the case of one poisoned per os. Again, whether the serum of an animal dead a short time, after poisoning per os, gave a better precipitation than that from one in which the poisoning had been more chronic. Such had been the speaker's experience, although such a result would not have been expected. With regard to the agglutination reaction, apparently an appreciable amount of ricine was left in the circulation, and it was frequently possible to get a nice agglutination test by using the washed red cells of some other animal, and putting up three tubes—one containing a saline suspension of washed red cells to which a certain quantity of ricine had been added; another containing a suspension of red cells only; and a third containing a suspension of red cells, to which was to be added a fairly large quantity of serum from the poisoned animal. In the case of the first there would be a marked clumping of the red cells which would sink, leaving a clear supernatant fluid. In the second a mere sedimentation; and in the third a number of minute clumps varying in size and number according to the quantity or potency of the serum employed.

Mr. TOOPE mentioned a case of castor poisoning in pigs, due to the grinding of the bean with a common grade of barley. The pigs received the meal early in the morning, and at noon when he visited the sty he

found five pigs dead. He first thought he had to deal with anthrax; there was much diarrhœa, mixed with large quantities of blood. He microscopically examined the blood; there was no evidence of anthrax. The husk of the castor bean was present in the stomach in abundance. All the pigs that recovered took a week or ten days in doing so, some never recovered properly.

In looking up some notes I made on this case at the time I find the following facts noted:

"The five pigs that died had received a large quantity of the meal, which had been previously soaked all night in boiling water, they were being fattened and had been given about four times the quantity that the other eleven had. This accounted for the rapid death. They were fed at 5.30 a.m. and were dead at 12.45 p.m. that day.

Post-mortem showed indications of gastro-enteritis with considerable apoplexy of the posterior bowel, and rupture of the mucous membrane in several places. Skin discoloured from recent extravasations beneath it, etc. Vascular system generally empty or nearly so. Damages against the dealer were claimed and paid."

In another case, in which young animals had been fed with ground cake in the form of meal, there was no diarrhœa; on the contrary, there was obstinate constipation, which, however, might not have been entirely due to the castor bean, although the husks were present in abundance on micro examination. In this case the husks alone remained and had been used as a make weight probably.

Mr. H. A. MACCORMACK enquired in what part of the bean the active principle was found. Dr. Lander replied that there was no active principle in the husk. Continuing, the speaker referred to two cases of castor poisoning, one being fatal. The fatal case was that of a black and tan terrier. When he saw the dog it was violently sick, and purging was excessive, with a certain amount of blood. He could not diagnose the malady, but administered stimulants, the dog died during the night. He was unable to make a post-mortem. On subsequently questioning the son of the owner, it transpired that the dog had been playing with castor seeds and had been allowed to eat one, but only one. Apparently, therefore, one *ricinus communis* had been sufficient to kill.

Another case happened some years ago. A seedsman's foreman had found castor seeds in the refuse of some seeds he had been cleaning. He understood them to be poisonous, but not exactly how poisonous, and gave them to two young fellows who cracked the seeds, and each ate a couple of the kernels, which, he would remark, were of a pleasant, nutty flavour. The youths were next morning exceedingly "limp"; they had been unable to go to bed owing to sickness and purging. The speaker considered that the bloody discharge referred to by Mr. Toope and Mr. Upton was, he thought mainly due to the husks, which injured the mucous surface of the intestines. The husks were hard and flinty, and the injury produced when an animal swallowed them was quite comprehensible.

Mr. W. R. DAVIS referred to a case of a corn merchant who, being desirous of grinding castor seeds to mix with forage for horses, had consulted a medical man, by whom he had been informed that the seeds were quite harmless. In all innocence, the merchant ground the seeds and mixed them with the forage, and, in the result the corn merchant had to pay £300 to the purchaser of the forage for the loss of several horses. (Case reported in *The Veterinary Record*). The speaker would ask Dr. Lander if it were not a fact that many authorities held the castor seed to be non-poisonous. He recalled an account of experiments by a German (he believed named Baumgarten) who failed to poison animals by giving them castor seeds. The corn cockle seed also was said to be poisonous by some, and by

others held as harmless. He scarcely agreed with Mr. MacCormack's opinion that the rough surface of the castor seed husk caused discharge of blood. So great a discharge as referred to by Mr. Toope and Mr. Upton could scarcely have been caused by the sharp particles of the husk. As a boy he remembered that gorse or furze was ground and given with meal to horses. He believed the bleeding was not due to mechanical agents in the bowel, but to action of the poison on the arterioles and capillaries, with consequent rupture of the capillaries of the mucous membrane of the intestines.

The PRESIDENT remarked that Dr. Lander's paper would have the effect of eliminating, in the future, any indifference as to castor seeds. He was surprised at the amount of poisoning which Dr. Lander had obtained from the administration of ricine by the mouth; and he would suggest secondary considerations such as worms or other causes producing injuries in the alimentary tract, increasing the facility with which the mucous membrane would absorb poisons. Mr. Buxton had pointed out that hypodermic injection of ricine produced enteritis. If that were so, it would seem certain that ricine had a specific action on the intestines, and hemorrhagic enteritis might be produced without the additional local irritation of the seeds, which had been suggested as the primary cause of the hemorrhage.

With regard to the statement that the husk did not contain ricine, the point had been established recently, and was contrary to earlier belief. It was interesting to know that in seeds where the husk was in the largest proportion the toxic effect was least. It was also interesting to note that the seed with the most brilliant hue, the *ricinus Zanibariensis*, was the most toxic, although there might be no real association between the facts. On the question of treatment, drastic purgatives, such as pilocarpine or eserine would certainly clear the alimentary tract. But it had to be borne in mind that ricine produced great depression, and this depression was increased by drastic purgatives, so it should not be applied in general practice without previous experiment. In cases of suspected ricine poisoning a great depressant, such as eserine, might kill the patient. He would like to ask Dr. Lander whether, in his experience, he had found that red colouring said to be blood was not blood but was hæmoglobin. As the effusions were sometimes reddish-tinged, and the milk also, he wondered if ricine was capable of producing hæmolysis.

REPLY.

Dr. LANDER said the salient point seemed to be whether seed poisoning produced bloody purgation or not. He could only say that the "experimental" animals displayed no bloody purgation. After injection, however, the symptoms were, as Mr. Buxton had pointed out, more marked, and the lesions greater, than when the ricine was administered per os. In fact, Mr. Buxton had struck one of the remarkable features of the results of the experiments, namely, the great paucity of symptoms and lesions. The bloody purgation question was one that merited the attention of clinicians and pathologists. Speaking as a layman, he supposed it not impossible that there might be variation from species to species and animal to animal. He had been interested in learning the effects of castor seeds in the various cases mentioned. It was astonishing, in view of the various facts narrated, what a relatively enormous dose of ricine was required to produce serious disturbance in a cow. In regard to Professor Wooldridge's remarks on facilitation of absorption, the point was important. If the mucous membrane were not intact, the danger of castor seeds was undoubtedly greatly increased. He had been told that a rat which had received a dose of snake venom per os was afterwards punctured in the stomach by an instrument, with the result that death

followed; otherwise the case need not have proved fatal. Such circumstances had, unquestionably, great influence in determining the actual toxicity. With regard to the ingenious suggestion put forward by Prof. Wooldridge as to colour, colour might certainly be a danger signal. So far as experience carried the matter, he was inclined to think the poisoning power was to be associated with the size, he believed it likely that the sky-blue castor oil seed, which was large, would be poisonous. The inference as to size was not, however, inherently probable. As to hæmolysis, ricine was not a hæmolytic agent, but, he believed that with a powerful agglutination some expression of hæmoglobin from the densely packed corpuscles would take place.

In answer to Mr. Davis, he had certainly heard statements to the effect that ricine was not poisonous. He could not agree with the statements. In consideration of the fact that the true nature of ricine was not understood, it also appeared to him illogical to assert, as had been done, that "ricine" was not the toxic agent.

Mr. T. S. PRICE proposed, and Professor Reynolds seconded, a hearty vote of thanks to Dr. Lander for his interesting paper. The vote was passed by acclamation.

Mr. SLOCOCK proposed, and Mr. Samson seconded, a vote of thanks to those gentlemen who had brought forward morbid specimens. This also was passed with acclamation.

HUGH A. MACCORMACK, Hon. Sec.

SCOTTISH METROPOLITAN VETERINARY MEDICAL SOCIETY.

(NATIONAL V.M.A.—SCOTTISH BRANCH.)

The annual meeting was held in the Royal (Dick) Veterinary College, Edinburgh, on Saturday, 7th Feb., when the chair was occupied by the President, Mr. John Riddoch, M.R.C.V.S. Also present: Prof. Ainsworth Wilson; Messrs. John Cameron, Berwick-on-Tweed; D. McFarlane, Doune; P. Wilson, Lanark; A. Baird, Edinburgh; Andrew Boyd, Melrose; John Aitken, Dalkeith; J. Borthwick, Kirkliston; J. L. Cormack, Edinburgh; W. W. Pegg, Biggar; L. McLaren, Brechin; Robert Reid, Coupar Fife; John Storie, East Linton; Profs. A. Gofton and J. R. U. Dewar. Visitors: Messrs. G. C. Lancaster and J. Plunkett, students.

Apologies for absence were received from Messrs. James Peddie and A. Wallace.

The SECRETARY read the following letter:—

"Local Government Board, Edinburgh.
Feb. 6th, 1914.

Sir,—The Local Government Board have instructed their veterinary medical inspector, Dr. Gerald Leighton, to conduct a full enquiry into the question of establishing a uniform system and standard of meat inspection for Scotland, and to present a report thereon.

Should your Society be desirous of stating their views on this question, the Board will be glad if they will appoint one of their members for this purpose, or submit such views to the Board in writing.—I am, sir, your obedient servant,

(Signed) DAVID BROWN, Assist. Sec.

Mr. STORIE thought it was desirable that the Council should appoint one of their number to represent them at the enquiry. He moved that it be remitted to the Council with powers.

The SECRETARY said this was a matter of very great importance, and it might be advisable to receive a report from the Council.

Mr. MACFARLANE suggested that they should ascertain from Dr. Leighton more definitely the nature of the information required.

Mr. P. WILSON thought they should say that they desired a uniform system of meat inspection for Scotland, and would be pleased to consider any rules or regulations which the Local Government Board might draw up, and give them any assistance possible. They could not do anything until they knew what rules and regulations were proposed, unless they were asked to draw up these rules.

The SECRETARY said the Board wanted their views on the question.

Mr. P. WILSON said the Society had no objection to there being a uniform system of inspection, but if Dr. Leighton was to prepare a report they could do nothing till they knew what it would be.

The SECRETARY said that Dr. Leighton looked to the veterinary profession for data on which to draw up his report. They should meet him sympathetically and do something in the matter.

Mr. CAMERON said he objected to the word "Scotland." They had too much of the Home Rule business of making one law for Scotland and another one for England. What they wanted was a national system. They gloried in their united profession.

Prof. GOFTON said that this letter was of importance, and he hoped they would give the Council powers if need be to consult others outside the Society so as to make the evidence comprehensive.

Mr. STORIE thought it was unnecessary to consult outsiders.

The letter was then remitted to the Council with powers.

ADMISSION OF PRESS TO MEETINGS.

Mr. STORIE, speaking of a letter he had sent to the Secretary, said he thought it of importance that the newspaper press should be represented at their meetings for the benefit of the agricultural public. Anything purely private could be taken *in camera*. He thought it was extravagant to arrange for a special report as at present.

The SECRETARY said it was advisable to continue the present practice of depending upon their own reporter, as the newspaper press gave very brief reports, and reported only what suited themselves.

Prof. GOFTON said that, if desired by the members, the Secretary might be instructed to prepare a report of the proceedings to the public press, but many of their meetings were of no interest even to the agricultural public. The late Mr. Young, editor of the *North British Agriculturist* was a honorary member of this Society for a number of years, and although he received an invitation to every meeting during his (Prof. Gofton's) secretaryship, he could remember him being present at only one. He put it forward as a suggestion that when they had matters that could fairly be reported they might instruct the Secretary to send a report to the newspapers.

Mr. MACFARLANE said it was apparent that if they discontinued their present system of reporting they would be unable to publish a detailed account of the proceedings. It was, however, desirable that the agricultural papers should either be asked to send a representative to their meetings, or that the Secretary should furnish them with a report.

The SECRETARY said he could prepare a report for the Press if necessary, but all they had expended in this way during the year was £2 8s. 7d. It was absolutely necessary to have their own reporter, whether public Press reporters came or not.

The subject was then left over till next meeting.

New Member. Mr. Wm. W. PEGGIE, M.R.C.V.S.,

Biggar, having been duly proposed and seconded, was unanimously admitted a member of the Society.

The CHAIRMAN said it was suggested that those who propose new members should see that the men who were willing to join the Society should attend the meetings.

Mr. CAMERON said he did not know if he could agree with the condition that new members should pledge themselves to attend. In the case of many who were working single-handed it was sometimes impossible to put in a single attendance in the course of a year. He excused them for that, but he excused none in the profession for not being a member. Every man should be a member of some Association so that his influence might be felt when necessary. If he paid his subscription it was his own look out whether he attended or not.

The subject then dropped.

The HON. TREASURER then made his annual financial statement, and added that the thanks of the Society were due to Mr. Peter Wilson for his help at the Lanark meeting, and also to the College for housing them there.

Prof. GOFTON moved acceptance of the financial statement, which was seconded by Mr. Macfarlane and agreed to.

REPRESENTATIVES TO THE COUNCIL N.V.A.

On the motion of the Secretary, it was agreed to re-elect Prof. Bradley and Prof. Gofton as representatives to the Council of the National Association.

PRESIDENTIAL ADDRESS.

Mr. J. RIDDOCH, M.R.C.V.S., Edinburgh.

Gentlemen,—I thank you for the honour you have done me in electing me to the Presidential chair, but it is with some diffidence that I accept such a responsible position. I shall, however, do my best for the success of the Society during my term of office.

There is a series of articles appearing just now in *The Journal of Comparative Pathology and Therapeutics*, by Major-General F. Smith, which affords very interesting reading, and which describes the state of the veterinary profession in ancient Egypt—the birth-place of the sciences—and also in Greece, Rome, and other countries, and gives the history of the profession down to our own era, and the author says "It is a remarkable fact in the world's history that the medical and surgical treatment of animals has always been regarded as a contemptible occupation and beneath the dignity of the educated mind." I believe this was due to the fact that before veterinary colleges were established, and for a considerable time after, the treatment of animals was undertaken by ignorant empirics, who played largely on the gullibility of their clients. In the early history of veterinary science too in this country, men often joined the College late in life. The late Professor Baird once told us of one man who gained his diploma when he was over fifty years of age, and who exclaimed "What a start in life I have got!" It is quite different now; the men who are entering the profession to-day are young men of education and gentlemanly demeanour, and will compare favourably with those of the medical or any other profession. We even find medical men now competing for, and obtaining, veterinary appointments. We surely need some kind of trade unionism to protect our interests. The raising of the standing of matriculation and increasing the period of study has no doubt raised the status of the veterinary surgeon and given him a better position in the estimation of the public.

The veterinary surgeon of to-day has to be well up in all animal diseases, and in methods of treatment which

were unknown comparatively few years ago. Such terms as opsonins, anti-bodies, autogenous vaccines, complement fixation, were unknown when some of us were at College. The veterinary profession has progressed side by side with the medical profession. When the medical profession raises its standard of matriculation, the veterinary profession invariably follows suit. I am quite in favour of the veterinary student being equal in education to the medical. The general public have an idea that the doctor has a superior education to that of the veterinary surgeon. It would be well if we could disabuse their minds of that fallacy. The matriculation examination is exactly the same for both professions. Our's is rather the harder, as all the subjects have to be passed at one sitting. I understand that the medical profession are about to raise their standard of entrance examination, and I have no doubt the veterinary standard will be raised too. We cannot afford to stand still. Every science and profession is advancing, and we must advance with the times. As time goes on more and more will be required of the veterinary student. There is a proposal just now to institute a Public Health diploma similar to the D.P.H. in human medicine, with an increased period of study.

Laboratory work is more and more in demand, and in order to obtain public appointments it is almost necessary to attend a post-graduate course in bacteriology and seropathy. The time may soon come for specialising in certain branches of our profession.

It is regrettable that our teaching schools should be in such a low condition financially, but there is a prospect of the Government assisting the teaching of our profession as they have assisted other branches of education. We need research laboratories connected with all our Colleges; there are still some obscure diseases and diseased conditions which need to be investigated.

The innovation of the motor car has no doubt hit some veterinary surgeons pretty hard. The prancing carriage horses—the best paying class of patients—are being replaced by the fast and luxuriant motor car. Motor traction is also largely coming into use for commercial purposes, and you will hear people say “there will soon be no use for veterinary surgeons.” I do not believe, however, that horses will ever disappear from this country. Then there are other classes of patients. Diseases of cattle and sheep are receiving more attention to-day than ever they have before, and there is a large and ever-growing number of household pets to attend.

For those entering the profession there are some splendid colonial appointments. The position and status of the veterinary surgeon in the Army has been greatly improved of late years. The veterinary surgeons on the Board of Agriculture are likely to get their salaries increased and their status improved, as there is a considerable difficulty in getting men to fill the various posts, and when the Milk and Dairies Bill becomes law, as we hope it soon will, there will be a number of veterinary surgeons appointed throughout the country to carry out the Tuberculosis Order. It is almost a scandal that legislation on this subject has been so long delayed when so much tuberculous milk is being supplied to all our large towns.

The annual number of deaths of veterinary surgeons in this country during the last few years has greatly exceeded the number of young men entering the profession, so much so that there is a dearth of veterinary surgeons at the present time, and many practices are remaining vacant. Taking all these things into consideration, I think the prospects of the men entering the profession to-day are as bright and promising as ever they have been in the profession's history.

We hope to see the Tuberculosis Order considerably extended in the near future. The Board of Agriculture know what is wanted, but on account of the great

opposition by local authorities and others who feared the expense, they had to make only a small beginning. The expense, however, will not be anything like what was anticipated. Sixty thousand pounds a year were set aside by the Treasury for their half of the compensation, and up to the 24th of January last, when over 4,600 animals had been dealt with, and the Order had been in operation for nearly nine months, only £4,500 were required, so that there will be a big surplus at the end of a year, perhaps somewhere about £50,000. Many animals that are not included in this Order are coughing up large quantities of expectorate containing tubercle bacilli, and spreading the disease broadcast. This is especially the case when animals are at grass. A tuberculous cow grazing in a grass field and coughing frequently tuberculous expectorate is literally sowing that field with tubercle bacilli.

A case of this kind came to my knowledge a few years ago. A tuberculous cow coughing up large quantities of expectorate, teeming with tubercle bacilli, was removed from one of our city byres, and was grazed a whole summer in a field near Edinburgh along with two colts. The cow was killed at the end of the season and the carcass was tuberculous throughout. About a year after the slaughter of this cow one of the colts had to be destroyed on account of tuberculous disease. That colt was not brought up on cow's milk, and I think there is good reason to assume that it was infected by its association with the tuberculous cow, which during the whole summer was polluting the grass by her expectorate, and perhaps also by her urine and faeces. One such cow in a grass field is capable of infecting a whole herd. Until all such animals are included under the Tuberculosis Order, there will be little headway made in eradicating the disease. Let us hope that in the near future this Order will be greatly extended so as to include all animals voiding tubercle bacilli in any manner whatever, and that a more liberal compensation will be allowed so as to induce dairymen and farmers to notify suspicious cases.

Mr. STORIE proposed a cordial vote of thanks to Mr. Riddoch for his interesting address.

Mr. CAMERON, in seconding, said that even the last point about the tuberculous cow was worth a great deal. —The motion was adopted.

“MAN AND MICROBE.”

Mr. STORIE opened a discussion on the paper he had read at Lanark on the subject of “Man and Microbe.” He said his chief idea in writing the paper was to bring the subject of bacteria before them in as plain and practical a manner as possible. Many looked on bacteria as something beyond them, and not quite in keeping with their other professional matters, but if they studied the subject they would find that bacteria were just like other organisms—he was almost inclined to say other animals, as perhaps they were more like animals than vegetables in their habits, but he must go according to the text books. They breathed. They should therefore apply the general laws of living organisms to them, especially those of evolution and heredity. One of the important items he mentioned was their economic value—their great value to the manufacturer in many articles. Then they must look on the control of them in regard to their food supply. They could not be fed in this country if it were not for arrangements made for preventing bacteria affecting the food imported into this country.

In regard to milk, bacteria was one of the most important subjects. The disclosures made by Dr. Stiles in his paper read before the British Association, since the Lanark meeting, had shown them the great importance of dealing with the tubercle bacilli in milk,

Some thought Pasteurising of milk spoiled its feeding qualities, although not damaging it to such an extent as to make it unsuitable for infants' food. With regard to toxins, Prof. Gofton at Lanark thought he was overstating the case, but he would read what Professor M'Fadyean said about toxins—"The pathogenic effects of bacteria are almost entirely ascribable to substances which, though elaborate, were manufactured. These were the so-called toxins." Another thing he (Mr. Storie) had mentioned was not taken much notice of in their profession, but more in the medical profession; he referred to the action of auxetics on phagocytes which were believed to destroy bacteria. That subject was being opened up just now, and was of intense interest. The M'Fadyean researches were well worth reading in regard to this subject. He had no experience of nuclein, but he believed it acted on the phagocytes. With regard to pathogenic bacteria, he would like to read a few lines he was afraid to read at Lanark—"Pathogenic or disease producing bacteria. Division into saprophytes and parasites—no hard and fast line can be drawn. Saprophytes may cause disease and may become parasitic under certain circumstances. All bacteria must have had a common origin. Evolution must have been at work amongst them just as in other living things of a higher order. Seeing that bacteria are so low, in fact the lowest known in the scale, and that since they multiply with such tremendous rapidity, they should be the most susceptible of all organisms. You can have a thousand successive generations in a fortnight—equivalent to a thousand years in the life of a wheat plant. What extraordinary variations could be produced in wheat in that time! Darwin believed in the slowness of the process of change in living things. *Natura non fecit saltum*, Nature does not leap, being a favourite saying of his, but we know that nature does leap. Bacteria must be particularly susceptible to changes of environment, a change in their food for instance; a chemical change in food and pasture might affect their own composition so thoroughly as to produce a pathogenic from a harmless form very rapidly. New types of a certain beetle have been produced in America quite suddenly by subjecting the creatures or their eggs to exceptional conditions of temperature and the like, and another experimenter has caused limitations in plants by injecting chemicals into the seed cups at the time of the formation of the seeds. Seeing this can occur in higher organisms, might not many of these sudden and obscure outbreaks of contagious disease be accounted for in this manner. Why should evolution not hold good now as it has done from the beginning."

The next thing he referred to was serums. It was really wonderful the extraordinary number of serums they could procure now as a means of treating disease. They had just to take up Parke, Davis & Company's list to see what a number of serums could be supplied, and he believed a great many of them had been successfully used. In regard to drugs, it was considered he was belittling their power too much. He repeated that they had been far too much used in the past, and that he thought they would be less used in the future. In regard to the treatment of bacterial disease, he did not think they had much effect.

Mr. CAMERON said this subject was both wide and important. He felt it was difficult to keep pace with the manufacturers of all these anti-toxins. It was comparatively easy for them to manufacture the anti-toxins and put them on sale, but sometimes after a big dose of medicine the disease reappeared. All these new anti-toxins cost a lot of money, and their clients were getting poorer. The result was that unless they could cure thoroughly every time at moderate expense they did not give much encouragement to go in for these high priced medicines. There were times, however, when it was their duty to place reliance on medicines,

and to make certain that they had the right quality of drugs.

The SECRETARY said Mr. Storie should be thanked for his remarks. The bit he read to them which had been omitted from his paper was quite valuable, and quite the most original part of his paper. He was perfectly right in saying that less drugs were being used. In these bacterial diseases the best practice he thought was simply to get the animal into as normal condition as possible, to keep the natural passages open, and give fresh air and natural surroundings. In that way they would get better results than with any amount of medicine. But it would always be the function of the veterinary surgeon to prescribe what these conditions of treatment were, and his applied knowledge would always be an invaluable aid to the stockowner.

Prof. GOFTON said he would refer to the two points which Mr. Storie had taken up bearing on the remarks he (Prof. Gofton) made at Lanark. With regard to toxins he was really at one with Mr. Storie. He was not aware that he ever disputed that the majority of organisms operated by means of toxins, but it did not follow that all did, and that was the point of his remarks at Lanark. There was a possibility—more than a possibility in some cases—that the organisms operated by methods other than through toxins, but the general statement was true that the majority did operate through toxins. Drugs were being used less and less he agreed, but the principles of treating syphilis by salvarsan (606) opened up a new line of drug treatment, and the preparation of the drug was entirely on new principles. Apart from that, one must admit that drugs were frequently valuable accessories in treatment by serums and vaccines. While drugs in the past had been abused, there was still valuable scope for their use, and it might be that the future would show that methods were open to them in the use of drugs in treating disease that at present they had no notion of. He would not speak of the evolution of bacteria, because he did not feel he was in a position to say anything about it. One could quite conceive that evolution did take place very rapidly in bacteria, but the subject at the present time at all events, was in a considerable measure speculative. There were very few facts to which one could refer as definite evidence that evolution did take place, and he did not feel that at present he would like to express any opinion on that subject.

The CHAIRMAN said they were very much obliged to Mr. Storie for his paper which covered so much ground. It must have cost him a great amount of thought and reading up. There was no doubt that bacteria followed each other generation after generation in so rapid succession that there was ample opportunity for evolution—far more than in the higher life. It was suggested that some of them might arise spontaneously according to Prof. Schäfer. That opinion would not be universally accepted, but the subject deserved further investigation.

Mr. STORIE, in reply, said he was disappointed that more members had not taken part in the discussion, but the subject might be taken up on another occasion.

A NATIONAL MILK AND DAIRY BILL.

Mr. JOHN CAMERON moved "That this meeting of the Scottish Metropolitan Veterinary Medical Society respectfully requests the Council of the National Veterinary Medical Association to take into their earliest possible consideration the subject of a National Milk and Dairy Bill, and we hope they will request every provincial veterinary Society to consider and formulate their ideas as to the appointment of veterinary inspectors to examine and report on all milch cows, whose milk is used for human food. Also all the various other points connected with veterinary procedure and inspection which should be stated in a Milk and Dairy Bill, which could be commended to give practical national

satisfaction. Having received these said provincial reports, that the Council of the National Veterinary Medical Association consider and formulate the same in accordance with the majority of opinion expressed; have it printed and for sale to all members of the veterinary profession." He said the veterinary portion of a Milk and Dairy Bill which would be practically satisfactory both in theory and practice was a subject which had engaged the earliest consideration of all Veterinary Societies, time after time. They had discussed it again at one of their meetings last year. It was a subject at the first, the last and other meetings of the National. Every milch cow should be brought under the procedure of the Bill. The need for a Bill on lines very different from anything which had previously been presented, was well illustrated recently in extracts from a paper by Dr. A. Philp Mitchell, of the Royal Hospital for Sick Children, Edinburgh, which appeared in *The Scotsman*. The complete paper was well worth reading in *The British Medical Journal*, of January 17th, 1914. Those who were members, or had read the discussion at last year's National would observe that they made special allusion to the very dangers which Dr. A. Philp Mitchell had so practically demonstrated. They would observe that Dr. Mitchell did not discuss the recent Milk and Dairy Bills, but he pleaded for satisfactory veterinary inspection of all milch cows. A useful aid to their correct diagnosis of this subject was to remember that Edinburgh, Glasgow, Manchester, Sheffield and a few more of their large centres of population would wait no longer. They got private Milk and Dairy Bills for themselves, and thereby a greatly improved procedure had been carried out. But they complained of the bad results from the surrounding districts. He hoped the serious results which were brought to light and notice by the doctor's investigations at the Edinburgh Children's Hospital would stimulate the apathetic public to put their shoulder to the wheel and demand that urgent necessary things should be done first. What was worth doing was always worth doing well, and was always cheapest in the end. As many distinguished veterinary surgeons from all parts of the world would attend at the International Veterinary Congress in London this summer, he hoped this Society would do their part thoroughly, and thereby help to have a National Milk and Dairy Bill on the stage of which neither the veterinary nor medical professions would need to be ashamed. He moved that this meeting accept the said resolution and agree that it be forwarded to the Assistant Secretary of the National in the hope that the Council of the National would give it their early and sympathetic attention and support.

Prof. GORTON said he had read this resolution carefully, and while in fullest sympathy with Mr. Cameron's motives, he did not feel at liberty to second. It seemed to him to lead nowhere. It asked the Council of the National to undertake an elaborate procedure which they would not be willing to undertake, and which was unnecessary, seeing that all their Societies were represented on the Council. It led nowhere, because after the Bill was drafted the Council were asked merely to print it and offer it for sale. After consultation with one or two members he had drafted an amendment which might be considered if Mr. Cameron was very anxious that steps be taken.

Mr. CAMERON said he was anxious something should be done to remove the stigma that would come upon them.

Mr. BOYD said that unless the fountain head was pure they could never expect good water. They must deal with the breeding herd if they wanted a pure dairy supply. No Bill would be of any use unless it contained a compulsory clause to test breeding herds.

Mr. STORIE said this was far too big a question to take up at such a late hour.

Prof. GORTON said it was undoubtedly a question for a whole meeting. He suggested that the matter should be remitted to the Council to arrange for early discussion on the whole subject.

Mr. CAMERON said that the subject had been frequently discussed, and there was ample printed material to enable the Council of the National to indicate the mind of the profession. But they really wanted to see what should be put in a Bill.

It was then agreed to remit the matter to the Council.

THE TAX ON MOTORS.

Mr. REID suggested that efforts should be made to get a reduction of the tax on motors used by veterinary surgeons, as was done in the case of doctors.

The CHAIRMAN said that had been frequently tried.

Mr. REID said they should peg away till they got it.

SPECIMENS.

Professor AINSWORTH WILSON showed the following specimens:—

Case I. Navicular Disease. Subject, an Artillery draught mare, aged 8 years, which went very lame in both fore feet at camp in July, 1913, accompanied by a high temperature, and symptoms which pointed to laminitis. The mare was returned to light work in about six weeks, but she was never quite sound.

Early in January acute symptoms reappeared, and the animal was destroyed on the 21st. The hoofs and bones of the lower limbs were exhibited. The navicular bones alone showed evidence of disease in the form of a rarefying osteitis, the holes on the posterior tendinous surface being about the size of a pin's head and half a split pea respectively, and the interior of the bones being considerably hollowed out. He drew attention to the absence of any sign of ring formation or contraction of the hoof.

Case II. Navicular Disease. Subject, a cart horse, aged 10 years, fell very lame in one fore foot in 1912. He suffered considerable pain, could bear no weight on the limb, and the toe merely touched the ground. An extensive inflammatory swelling appeared round the heel and coronet. Fracture of the os pedis or acute osteitis was suspected. Two months later the horse was destroyed, having shown no improvement. The os pedis and os corona were the seat of new bony deposits, but the primary and essential lesion was evidently an extensive carious condition of the navicular bone.

It seemed to him worthy of note that both these cases occurred in heavy horses, in both the cartilage was removed, and the bone roughened without the perforans tendon being involved.

Case III. Deferred fracture of the Tibia. Subject, a three-year-old van gelding with the following history. Entered a large stable on Jan. 1st, 1914; kicked in the stall above and inside the hock on the 21st, the wound being trifling, and associated with little or no lameness; put to work on the 28th. At midday on Feb. 1st the groom who was watering the horse in the next stall heard the young horse slip and fall. When examined, a piece of bone was protruding through the skin on the outside of the leg, a hand span or more above the hock.

The specimen showed a very long oblique fracture. The practice in this stud had been to place horses so kicked in slings for about three weeks, but in this case precautionary measures were neglected.

It seemed very probable that a starred or deferred fracture without displacement had existed from the outset.

A fore foot of the same horse (exhibited) showed two small sidebones in process of development.

Disease in Certified Meat.

The Medical Officer of Health for the Port of London, in a report to the Corporation, mentions that certain pig carcasses affected with tuberculosis were found among the meat which arrived recently from Flushing at Queenborough. They all bore the official certificate of the Netherlands Government as approved by the Local Government Board. One carcase, affected similarly, arrived from Ostend. It bore the Belgium Government certificate.

A consignment of Australian meat, consisting of 398 buttocks, proved to contain, to the extent of 12.3 per cent., "worm nests" (*onchocerca*). The meat bore the official certificate of the Australian Commonwealth.

Synthetic Milk.

Milk from Soya beans is not a new idea. Several years ago an attempt in this direction was made, but was negatived, for one reason, by the distinctive flavour.

It is announced in the public press this week that this, and other difficulties have been overcome. It is stated that the fluid, as far as its appearance is concerned, is quite indistinguishable from rich cow's milk, is delightfully smooth on the palate, but to some persons the taste seems slightly different from that of ordinary milk.

Casein obtained from the soya bean is the basal constituent of the new milk. All oil and waste matter are removed and only the pure casein left; to this basis are added in exact proportions fatty acids, sugars, and salts, and the difficulty of producing a perfect emulsion has been completely overcome, the new fluid satisfying every test in this direction, even to the extent of refusing to "cream."

In order that the synthetic milk may approximate to the real milk, bacteria of the required strains, including the lactic acid bacilli, are introduced to the fluid and permitted to act until it reaches exactly that "maturity" at which fresh cow's milk is obtained. This condition is proved by the fact that excellent cheese and "butter" can be made from it.

The milk can be made up in any proportions desired, that is, with more or less casein, fat, sugar, or salts, and thus can be supplied to children and invalids according to a medical prescription. Finally, the new milk can be produced more cheaply than can ordinary milk.

"Who takes or uses."

The following case presents an unusual feature in such prosecutions:—

At Chelmsford on Friday, 13th inst., Gladstone Ward was summoned for using the title of dentist, not being registered under the Dentists' Act, 1878, and not being a legally qualified practitioner.

Mr. P. J. Ward said the prosecution was brought by the British Dental Association. Defendant started business in Chelmsford, at premises in Tindal Street, which were described as "The Anglo-American Dental Surgery," and on a plate outside the premises were the words "G. Ward. Teeth extractions." Last year defendant applied for membership of the Chelmsford Unionist and Conservative Working Men's Club, and for that purpose had to sign his name in a book, together with a declaration according to the rules of the Club. On September 15th defendant signed and described his occupation as "dentist." As apparently he had heard that some stir had been made, he applied to the Committee of the Club to alter his description. In the presence of the secretary defendant added the letters "ry" to the word "dentist." The witnesses in the case, Mr. Ward added, were all called against their will, and on subpoena of the High Court.

W. T. Brown, clerk to the solicitors to the B.D.A., produced the Dentists' Register and the Medical Register, in which, he said, the defendant's name did not appear.

Mr. C. H. Aubrey, for the defence, said the Act only forbade the assumption of the description or name of dentist, but did not stop anyone from practising dentistry. The prosecution was brought about by the fact that there was another dental practitioner in the Club, and there was a little bit of feeling in the matter.

The Mayor (Alderman G. W. Taylor) said it was not a flagrant case, but at the same time dentists and the public must be protected. Defendant would be fined 40s., and costs £1 9s. 6d.—*East Anglian Daily Times*.

A joint sub-committee of the Market and Public Health Committees of Edinburgh Town Council have recommended the setting up of a separate veterinary department for the city under a duly qualified veterinary inspector, and transferring to the new department the veterinary inspectors at present in the Medical Officer of Health's department. It is considered that the proposed new department will attract more competent men to the service, and that there will be better chances of promotion for the officials.

PARLIAMENTARY.

SWINE FEVER AND SERUM EXPERIMENTS.

In the House of Commons on Wednesday, March 18, in reply to a question:—

Mr. RUNCIMAN said: One experiment had been begun up to the present, and others are in contemplation; over 100 swine have received injections of serum, and are now under observation. It is inadvisable at present to disclose the whereabouts of the premises where the experiment is being made, but the results will be published in due course.

The Royal Sanitary Institute.

A Sessional provincial meeting will be held on Friday March 27th, in the University, Birmingham, (Edmund St.), at 7.30 p.m., when a discussion will take place on "The Certification of Milk and its Effect on the General Milk Supply," opened by Wilfred Buckley, Esq., of Basingstoke. The chair will be taken at 7.30 p.m. by Louis C. Parkes, M.D., D.P.H.

Those proposing to attend and take part in the discussion, can obtain a copy of the paper to be read, on application to the Secretary of the Institute three days before the meeting.

LOWE.—At Bangalore, India, on the 21st February, 1914, the wife of Capt. W. Cecil Lowe, A.V.C., of a daughter.

The following inventory was included in the list recorded in the Sheriff Court books of Argyllshire during February:—JAMES DOUGLAS, M.R.C.V.S., of Messrs Cook & Co., Ltd., Calcutta, and who resided at Erich Bank, Kirn, £39,680.

OBITUARY

A. PATON, M.R.C.V.S., Clarendon Rd., Leeds.

Graduated, Glas: July, 1888.

Mr. Paton died on March 13, from chronic nephritis. Aged 55 years.

The death is reported of Mr. Leonard Thompson, B.Sc. M.R.C.V.S., of Retford, Notts., but no particulars are to hand. He graduated at London, July, 1909.

The late Mr. W. J. Watt, M.R.C.V.S.

The funeral of the late Mr. W. J. Watt and his wife took place at Norwood Cemetery on Thursday, 12th inst. There was a fairly large attendance at the cemetery, which included Messrs. H. Lomas, J. W. Brownless, and A. Dunbar, M.R.C.V.S., and many local and personal friends. There was a large number of floral tributes—from the children and relatives, and from firms and employees with whom Mr. Watt had been connected, and from personal friends.

Mr. Watt was born in Virginia, U.S.A. He came to Fulham Road in 1904, and later took over the practice of Mr. Sam Bignold, at Lillie Bridge, on his retirement. He had been in bed on the Tuesday, apparently with influenza, but was out again on Thursday, and died suddenly in the forenoon on Friday. His wife took his death very much to heart: serious nervous symptoms followed and death occurred on the Tuesday. They leave four children, two boys and two girls.

CORRESPONDENCE.

TRANSMISSIBILITY OF TUBERCULOSIS.

Dear Sir,

"Fools often walk where angels fear to tread," and I fear I may be one of the former in writing this letter. I cannot, however, allow Mr. Leeney's letter in your last issue to pass without notice.

In the early part of his letter he says "that it has never yet been definitely proved that any human being has been infected by the consumption of cow's milk." I think that this remark may apply equally to many other diseases which are accepted by all professional men as being infectious or contagious, and probably with less theoretical proof to support their belief.

Tabes mesenterica, I believe, is recognised as an infantile tuberculous condition of the bowels, and was believed to be caused by the using of cows milk, long and long before the bacillus tuberculosis had been recognised; now, of course, it is an accepted fact except by a few.

Surely Mr. Leeney cannot suggest that experimental inoculation is the same as natural infection. Does he know anything of the opsonic index theory? This, to my mind, proves conclusively that the conditions of the body are not always the same, and we have yet to learn which condition is most favourable to certain bacilli.

If tuberculosis has been produced by inoculation or feeding upon tuberculous material, it should be sufficient cause for legislation to prevent the use of tuberculous products for human consumption, or for that of lower animals, at least in a raw state.

I always court discussion, but strongly condemn a professional man who, like Mr. Mond, endeavours to make a name with the lay public by undoing the strenuous labours of generations of scientists.

In my presidential address I made allusion to this matter, and an eminent medical bacteriologist present corrected me when I alluded to Mr. Mond as a medical man, he informed me, however, that he was the son of a chemist who made a heap of money.

I trust that Mr. Leeney will think twice before he rushes into print to defend a layman against his professional confreres.—Yours faithfully,

J. CHAS. COLEMAN.

Swindon.

MOTOR TAXES: PETROL REBATE.

Sir,

Following Mr. Bindloss's example, I wrote to our M.P., Mr. Arnold Ward, re motor taxes and petrol rebate for veterinary surgeons, and have received promise of his help when the Finance Bill comes before Parliament. He asks for publications containing the previous history of the matter. Can you, or any of your readers, tell me where these can be obtained?—Yours faithfully,

A. C. WILSON, Capt. A.V.C., (Ret.)

Berkhamsted, March 19th.

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

No. 1342.

MARCH 28, 1914.

VOL. XXVI.

THE NEED FOR STUDY.

It was once a proverb in our profession that a man must be a good castrator and obstetrician to be a successful country practitioner, and a good judge of lameness to succeed in the town. Like most such aphorisms, this one was never absolutely true, but for many years there was an element of truth in it. There were many practices in which the most important part of the work came under one of these two headings.

Our profession has changed greatly since then. Obstetrics is certainly no more important in the country than it used to be—perhaps less so to us. There is a tendency—not always a wise one, we think—to relinquish castration; and the importance of lameness is dwindling everywhere. New work is coming into our hands to counterbalance this, but all of it requires new knowledge. The canine and feline practice that is now so important in town and country alike, has forced us to study new patients, of whose diseases most of us knew very little twenty-five years ago. And even in our old patients there is now much more for us to know than there once was. Many more diseases are recognised, and in many cases the diagnostic methods are far more delicate than in the old days. Preventive medicine, which now concerns most practitioners more or less, is largely carried on by these finer diagnostic methods. Throughout all our work the demands upon the practitioner's knowledge are greater than before. This is true to-day, but it will be much more true a decade hence.

Veterinary practice is rapidly becoming permeated with special subjects, some so complex as only to be fully grasped by specialists. Nevertheless, the practitioner is required to possess a sound, if in some cases an elementary knowledge of all. Clinical medicine and surgery, bacteriology, protozoology, parasitology, vaccine and serum therapy, hygiene, dietetics—the man in practice, though he may not study all of these very deeply, cannot afford to neglect one. The more he learns of each, the better he will grasp the daily problems of his work.

But there is now so much for the clinician to know that very few will attain true competence without a little reading practically every day. General Smith, in a well-considered address to Army officers a few years ago, suggested one hour daily as probably sufficient, which, if backed by observation and practice, it should be. Something like that is essential to the practitioner, unless he is to fall behind the times in some respects.

ALOPECIA TOXICA.

The accompanying photographs are of a bay gelding belonging to a cavalry regiment.

The animal after suffering from catarrhal fever was to all appearance convalescent when he was suddenly attacked with cedema of both hind legs, and the under surface of the belly. There was no digestive disturbance. The cedema disappeared in a few days and the coat became loose, so that it could be plucked out in handfulls. Finally the animal presented the appearance of baldness seen in the illustrations. It will be noticed that the long hair of the body, *i.e.*, mane and tail, also the coarser hair on the lower part of the limbs was not affected.

The horse fed well, and was apparently not at all disturbed by the condition. After about a month it has quite recovered, grown a beautiful new spring coat, and is again at duty.

J. R. HODGKINS, F.R.C.V.S., Capt. A.V.C.

Dublin.

THE TREATMENT OF CONTAGIOUS ABORTION WITH "BISSULIN."

Owing to the success I have had with the use of this agent, I think it right to place my experience at the disposal of my *confrères*. I have also had some communication with my friends, Mr. J. F. Healy, of Middleton, Co. Cork, and Mr. Allan Baker, of Bansha, Co. Tipperary.

I have singled out three special cases in my own practice for the subject of these notes.

The first case, in 1912, was in a herd of twenty-two cows, the property of a widow, near Limerick. Eleven of these cows had aborted, and the twelfth aborted within twenty-four hours of the time I began treatment, and the disease then stopped. In this case the infection was traced to allowing a neighbour's cow to be served by the bull on the farm.

In the second case, in 1913, there were eighteen cows, six of which had aborted, seventeen of which I treated, and the eighteenth was brought into the byre, subsequent to the treatment of the others. This cow received no treatment, and aborted after she had been in the byre a month. The cause of infection was again directly traceable to an outside cow.

The third was in the herd of the Earl of Dunraven, at Adare, and out of thirty cows ten had aborted, and one or two came in season regularly, but did not stand to the bull. In this case the bull, which was a prize Aberdeen Angus, had been

allowed to serve cows outside the owner's, and on examination he was found to be badly affected with infective granulomata of the genital organs, and the testicles were very much swollen.

I have also tried "Bissulin" with two or three mares which did not stand to the stallion, and had, in each case, vaginitis, and found it very successful.

Directions for the use of "Bissulin" are supplied by the makers with each package, but it is advisable in some cases to modify the treatment, taking into account the severity of the vaginitis, which is nearly always present. I have also found "Bissulin" effective in the cases of abortion where no vaginitis was apparent, and, in my opinion, in these cases the entrance of the germ is by the genital organs, despite the theories advanced against this opinion. Were it otherwise, local treatment would be of no avail.

In Mr. Baker's notes, he says "I have had most excellent results in the thoroughbred mares with which I used "Bissulin." It has also continued to be very successful in the cases of contagious abortion in cows," and writing later on, he says, "Just a line to let you know how the "Bissulin" is doing for me. I may say it has been an unequalled success both in cattle and in brood mares. I have treated about three hundred cows suffering from contagious abortion, and in every case the result has been most satisfactory. In thoroughbred mares it has been equally good. Whether used in the troublesome cases where there is an abundant white discharge, or in the equally annoying cases of an acid secretion of the vagina, the result is always gratifying. I have one mare which I showed you when you were over here that had suffered from a thick white discharge for five years, and she has been perfectly cured and is heavy in foal, due to "Bissulin" having cured the interior of the womb. I have several other cases of valuable mares treated with "Bissulin" and proving in foal, which were barren before using it. In all twenty-five mares."

"Bissulin" is put up in small conical pessaries for use in the mare and cow, and very little skill is required in using it in either of these animals, but in the case of the bull, for which it is put up in small cylindrical pessaries, there is sometimes a difficulty in inserting them into the sheath, and the bull should be, if possible, treated by the veterinary surgeon himself, but an intelligent herd is quite capable with a little demonstration, of carrying out the treatment in cows. In addition to the use of "Bissulin" the hind quarters of the cows, and their hind legs and tails, should be thoroughly cleansed and disinfected periodically, so also should the walls and floor of the byre and stable.

"Bissulin" has the advantage of being a non-irritant as well as a germicide and antacid, and is odourless, which is a decided advantage. "Bissulin" is made up of different fats and contains 25 per cent of strong Sozodol mercury.

The cases I have stated are only three of many, but they were all cases in which the disease had been rampant before treatment, and in each it had entirely disappeared after proper precautions had

been taken, and the cows which had previously been sterile proved in calf afterwards; several mares I have treated have also proved in foal, and the results I have had in my experience tally with those of Mr. Baker, extracts from whose letter I have given above.

Mr. Healy had also promised me some notes, but they are not to hand yet.

E. C. WINTER, F.R.C.V.S.

Limerick.

NOTES ON MAL DE CADERAS.

By Capt. A. L. FARRANT, F.R.C.V.S., M.R.S.I.LOND.

Synonyms.—Peste de caderas (Brazil), Mal de caderas, tummy-baba or tummy-a (Paraguay, Argentine), Flagellosis of equidae, trypanosomiasis of equidae.

Mal de caderas, disease of the rump or hind-quarters, is an epizootic disease of horses, mules, and asses occurring in South America. The trypanosome, which is the causal agent, was discovered by Dr. Elmassian, Director of the Bacteriological Institute in Asuncion, the capital of Paraguay. The organism, *Trypanosoma equinum*, was named by Vosges, of Buenos Aires, in 1901, shortly after its discovery.

The form and appearance of the trypanosomes are as follows:—The body is elongated, and usually blunt at one end with a flagellum at the other. Centrally there is a round or oval body, the nucleus proper. Behind this, and usually very close to the posterior end of the body, is a very much smaller body, the centrosome, blepharoplast, or kinetonucleus. From this centrosome arises the flagellum which runs to the surface, emerges, and passing forward forms the border of the undulating membrane. This flagellum is longer than the undulating membrane, displaying a free portion which is usually as long as the entire body. The end from which the flagellum protrudes is regarded as the anterior.

Trypanosomes are parasites of vertebrates ranging from fishes to man. They are confined to the blood, lymph, or cerebro-spinal fluid, and therefore, with one exception, the intervention of an intermediate host is necessary for their transfer. In the case of certain of the mammalian trypanosomes the carrier is known to be a fly. The transfer of trypanosomes by the invertebrate host is effected in two ways, the indirect or biological and the direct or mechanical. The former is wholly analogous to what takes place in the transmission of malaria by mosquitoes. The fly bites an animal suffering from the disease, taking up a number of trypanosomes with the blood. These are not digested by the fly, but go through certain biological processes, and may even apparently disappear as trypanosomes. At all events the fly, after the first few hours, generally ceases to be infective, and remains non-infective for several days. After this lapse of time, however, the trypanosomes within the fly resume their ability to infect any host which the fly may bite. Moreover, flies which have thus become infective remain so, so far as is known, for the rest of their lives, the trypanosomes continually multiplying within them. In the experimental work so far done, however, only a small proportion of flies—from 5 to 20 per cent. acquire this permanent infection, although in nature it is believed the percentage is much higher.

The second method of transfer is the direct or mechanical. If a fly bites a sick animal, and very shortly afterwards a healthy one, the latter may contract the disease. This is due to the fact that as a result of the first bite the proboscis of the fly becomes charged

with trypanosomes, and these are deposited in the wound made when the fly bites for the second time.

The experiment has been tried of allowing a fly to bite a sick animal, and then successively, two healthy ones. It has been proved that the first healthy animal to be bitten by the fly usually contracted the disease, whereas the second one did not. In other words, the fly cleaned its proboscis while biting the first of the two healthy animals. The ability to infect by the direct method is usually lost at the end of a few hours, but may be maintained for as long as two or three days.

In the transfer of an organism by the indirect method, while there may be more than one insect host, these, in the known cases, are closely allied species. In direct transmission it apparently makes but little difference what species of the biting fly is involved, the essential condition being that the interval between the bites of a sick to a healthy animal be only a matter of a few hours. The fly merely acts as a scalpel or hypodermic needle. Indeed, it has been found that the house fly, which cannot bite at all, can transfer *Mal de caderas, surra, and other trypanosome diseases by merely sucking alternately a raw surface on a sick and healthy animal.*

Knowledge as to what takes place with the trypanosome in the intermediate host is meagre up to date. According to Lacerda, *Mal de caderas* was imported into the island of Marajo, from there it spread as far as the State of Matto Grosso. This much is certain, that since 1860, *caderas* has caused such ravages in this particular State that horses and mules have all disappeared, and the natives are obliged to use cattle as draught animals, and even for riding purposes, young bulls are trained. At the present time the disease has greatly extended; it occurs in Brazil and Bolivia, throughout Paraguay, in the Argentine territories of the Chaco, Formosa, and Misioner, also the Argentine provinces of Corrientes, Santiago del Estero, and Catamarca. The epizootic is most prevalent in the marshy districts, and during the months that it rains least.

Animals susceptible. *Caderas* occurs naturally almost exclusively amongst horses, but by inoculation can be given to a large number of other mammals.

Let us first study the disease in the horse and mule, since it is essentially a disease of the equidae, and in them may give rise to very serious epidemics.

We have already seen that in certain parts of South America it is so difficult to keep horses and mules alive that cattle have to be used for riding purposes. Vosges mentions the case of a cavalry regiment which in June received 600 horses, of which only 100 were alive in the following November. Mules and donkeys, especially the latter, are more resistant than horses.

SYMPTOMS.

1. The first sign of the disease in horses and mules is lachrymation—or tears from corner of the eyes running down the face; this at first is slight, but in a great number of cases increases in amount until it becomes profuse. There also appears at the inner canthus a semi-gelatinous secretion.

2. Petechiæ or ecchymosis of the mucous membranes, chiefly those of the membrana nictitans, which is of a claret colour, ranging from 1-16th to $\frac{1}{4}$ of an inch, there may only be one or several, and, as the disease progresses they increase in size, and coalesce. To observe these changes the lids of the eye must be everted. (*This is very characteristic in the early stages.*)

3. Irregular fever, temperature 104° F. to 107° F., which only lasts for very short periods, during which the trypanosomes can be usually found if smears of blood are taken upon glass slides.

4. Urine voided tinged with blood in great number of cases, more so in the females of the present epidemic.

All authorities on this disease agree in stating that the organisms are not found in the urine, even when animal is affected with hæmaturia.

5. Penis of male projected from sheath for about six or eight inches, with slight erection, and the organ bent either to one side or the other; this condition is continuous in animals thus affected.

6. The skin, particularly of the neck and shoulder is often the seat of slight weeping eruptions; the patches, which are 1 to 1½ inches in diameter, are covered with small scabs, and the hair falls out in those places. It is probably due to the presence of these patches that, upon all the estates where the epidemic has fallen, there has been an increase to an enormous extent of collar galls and harness sores in spite of extra precautions to prevent it, and the mules doing less than their usual work.

7. Paresis or loss of power to control the hind limbs in the later stages is characteristic; although microscopical examination of the blood at this time fails to reveal the presence of the organism, but if injected into susceptible animals, a typical infection results. The disease is almost always fatal to horses, it lasts from two to five months in the horse; six to twelve months in mules and asses. There is rapidly advancing anæmia, emaciation, and great debility, although in the great majority of cases the appetite remains good throughout, no matter how high the fever may be. There is extreme pallor of the visible mucous membranes, followed a little later by a yellow tinge. From first to last there is a progressive wasting.

8. The severity and course of the disease depend a good deal upon the age and breed of the animal; for example, young mules that appear to have taken more to the equine side of their breeding are less resistant to the disease than adult healthy mules of common breed.

MODE OF PROPAGATION.

Mal de caderas can be very easily inoculated, a very small dose being sufficient, or to place traces of the virus upon the surface of a wound or excoriation. The ingestion of blood or an emulsion of an organ containing trypanosomes is not followed by infection, if there be no recent wound or abrasion of the mucous surfaces. Sexual intercourse does not give rise to infection, as in the case of dourine or mal du coit, and allied trypanosome disease of horses.

One would naturally imagine that *caderas* was spread by means of biting flies, as in the case of *surra* and *nagana*. This opinion has been held by nearly all observers, but is still denied by some, and it is not in agreement with the number of recorded facts as to the conditions under which *caderas* is propagated. Personally I believe the stomoxys calcitrans which is so prevalent in every stable, pen, or byre in the colony, is the chief means of the spread of the present epidemic.

Lignières states an epizootic of *Mal de caderas* which occurred on a farm in Paraguay, did not spread to a neighbouring farm, which was separated from the former only by a wire gauze partition.

The only fact upon which all observers are agreed is that the capybara (*Hydrochoerus capybara*) or caprincho which is very abundant in Paraguay and in the Argentine portion of the Chaco, along the banks of the small watercourses running through the cattle-rearing districts is the source from which the flies or other carriers of the disease probably obtain the virus. These animals are attacked periodically by an epizootic of an unknown nature; they lie about along the banks of the streams and die there. When the farmers in Paraguay find the dead bodies of capybara on their farms, they know that *mal de caderas* will soon break out among the horses. There is a striking analogy between this mortality among the capybaras which precedes outbreaks

of caderas, and that among rats which precedes epidemics of plague. (Capybaras are, I understand, the water rats of this colony).

PROPHYLAXIS AND TREATMENT.

Veterinary surgeons, estate managers, and horse proprietors should see that all animals are daily dressed with the following, in the morning for preference, with a view of keeping their animals free from the various flies, and thus to some extent preventing the animal from becoming infected: Kerosine 1 gallon, water 2 gallons, soap (soft or hard) 1 lb. Dissolve the soap in the water and add with continual stirring whilst water is boiling the kerosine, allow to cool, and then brush into coat of animal with body or dandy brush. Quinine, methylene blue, salicylic acid, carbolic acid, permanganate of potash, boracic acid, also intravenous injections of perchloride of mercury have all been tried in the treatment of this disease. As with nagana and surra, arsenious acid has given favourable results in some cases, but the improvement has only been temporary. Nuclein gave excellent results for a time, but later did not appear to exert any beneficial effect on the diseased animals. Salvarsan (606) proved useless, the animals upon whom it was tried quickly succumbed. Intravenous injections are being made upon some 30 animals, but at this stage it is too early to be able to offer any opinion either for or against the treatment to which they are being subjected. At a later date I hope to be in a position to offer some further information on the subject.

In animals found to be affected with the disease, before they have become very low in condition, I have had most excellent results by the administration morning and night of a mixture of pot. iodide and hydrarg. biniod, particulars as to doses, etc., I shall be most pleased to forward to any qualified brother practitioner; the animal while undergoing the treatment must be relieved from work of any kind, neither riding or hauling being permissible, as the animals appear to be unfit to cope with the disease and work at the same time.

ABSTRACTS FROM FOREIGN JOURNALS.

EPITHELIOMA OF THE JAWS IN THE HORSE.

Roquet, in an anatomo-clinical review (*Revue Générale de Méd. Vét.*) of this condition, says that it is one of the most malignant forms of cancer. It is found in adult or old horses. Generally it is situated upon the upper jaw; sometimes, but more rarely, upon the lower.

Among the symptoms are painful mastication, difficult deglutition, and a discharge of fetid saliva. The cancer is seen in the mouth, most frequently in the region of the fourth and fifth molars, in the form of fungoid friable granulations, which bleed easily. The teeth are deviated, loose, and sometimes detached. There may be invasion of the palate, nasal cavities, sinuses, and even of the skin of the forehead, with deformation of the head, a purulent fetid catarrh, and frequent nasal and buccal hæmorrhages.

The submaxillary and retro-pharyngeal lymphatic glands are invaded by cancerous adenites. The development of the epithelioma may also extend to the pharynx, soft palate, tongue, orbit, meninges, etc. The general condition rapidly becomes altered.

Histologically, the cancer appears as a squamous-celled epithelioma, usually having its origin in the gingival epithelium. More rarely it is a paradental epithelioma, originating at the expense of cellular accumulations which have remained unused in the formation of the teeth.

Epitheliomata of the jaws are distinguished from sarcomata by microscopical examination. Sarcomata are less frequent than epitheliomata, are found at all ages, and only exceptionally become generalised to adjacent organs.

Epitheliomata, on the other hand, are very soon accompanied by metastatic developments in the lymphatic glands. Their evolution is very rapid, and in two, three, or four months, the local lesions are very serious.

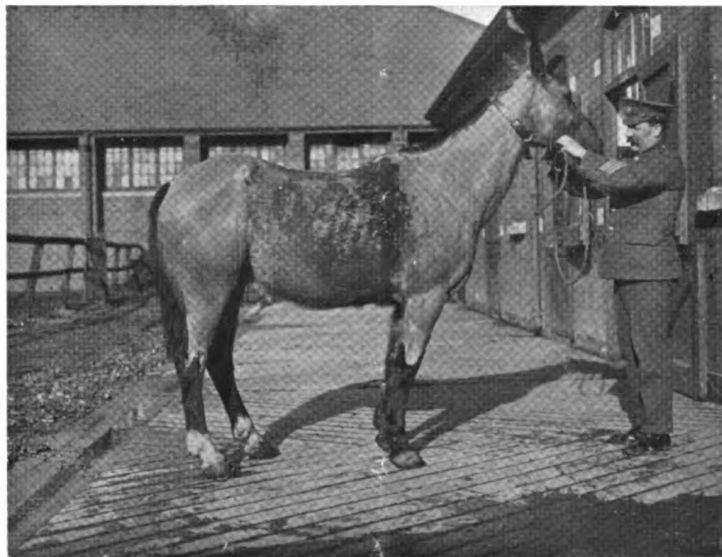

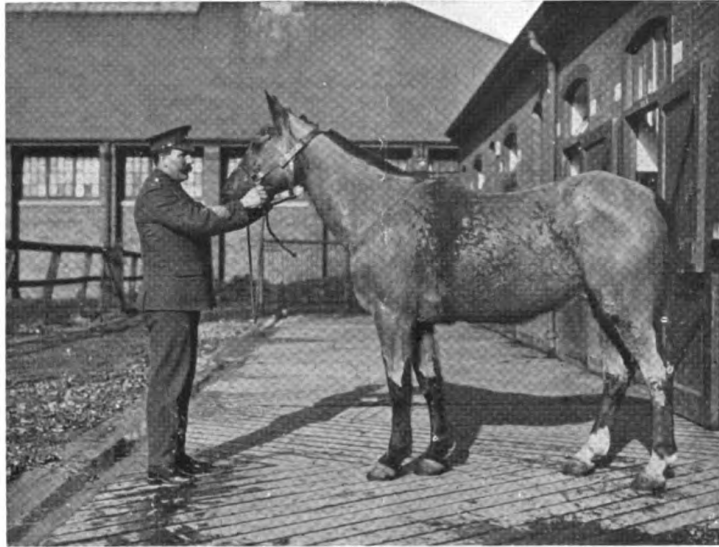

There is no effective treatment. The free excision of the lesions is inefficacious, as recurrences follow it.—(*Annales de Méd. Vét.*)

MANUAL TREATMENT OF THE BOVINE OVARY IN STERILITY.

Gebauer, an official veterinary surgeon of Dippoldiswalde, has published (*Deutsche Tier. Woch.*) an article upon this operation. The enucleation of the persistent and hypertrophied corpus luteum in the treatment of sterility was recommended by Hess and Zschokke in 1906, but Gebauer thinks, from the small number of reports upon it that have appeared in the professional press, that it is little practised by German veterinarians. Nevertheless, from the ease of its performance, and the successful results that have been attained by it, he thinks that it must ultimately be adopted by every practical veterinary surgeon.

Gebauer has performed the operation some hundreds of times upon cattle. From his experience he concludes that an examination of the ovaries by palpating them through the walls of the rectum should be undertaken upon every heifer which, after reaching the age of two years, still shows no signs of going to the bull. In farms on which cows are failing to conceive, the examination should be made upon each animal eight weeks after bulling, whether she has again come into use or not. Finally, the examination should be made upon every cow which, about eight weeks after calving, has not yet come into use for the bull.

The examination should be made by the rectum, and with one arm only. The ovary is palpated with the finger-tips, and is not drawn backwards while this is being done, but is allowed to remain in position. If a persistent and hypertrophied corpus luteum or an ovarian cyst exists in an ovary, an elevation is then distinctly perceptible to palpation. The ovary is then taken in the hollow hand in such a way that the corpus luteum to be removed or the ovarian cyst is placed against the thumb. The ovary is brought against the thumb by gentle pressure from all four fingers, so that the place to be operated upon can be felt distinctly. The cyst is broken, or the corpus luteum pressed out, by pressure of the thumb against the index finger. Even moderate pressure causes the extrusion of the projecting corpus luteum.

ALOPECIA TOXICA.

To illustrate note by Capt. J. R. Hodgkins, F.R.C.V.S., A.V.C.

When the operation is performed with one arm, there is no great danger of tearing away of the ovary. Nevertheless, the waves of rectal peristalsis, which set in at intervals of from 30 to 50 seconds, must be guarded against, and in that event the ovary must be released, even without completion of the operation, and then be searched for anew.

After extrusion of the corpus luteum, Gebauer advises compression of the ovary for about half a minute. After-hæmorrhages are rare. Gebauer has only observed two cases of protracted bleeding, both of which were successfully treated by the injection of ergotin.—(*Berliner Tier. Woch.*)

THE DEMONSTRATION OF THE NEGRI CORPUSCLES, AND THE DIFFERENCES BETWEEN THEM AND SINIGAGLIA'S CORPUSCLES.

Lina Negri Luzzani has published (*Annales de l'Institut Pasteur*) an article upon this subject. Numerous methods of examining the nervous system of animals suspected of rabies for the discovery of Negri's bodies have been described, and the author recommends the following procedure.

1. Gently scrape the surface of the hippocampus, or, in default of that, the cerebral or cerebellar cortex or the grey portion of the spinal ganglia.

Disassociate the scraping upon a slide in a dilute solution of acetic acid. Numerous isolated nervous cells are thus obtained, in which it is easy to recognise Negri's bodies.

2. If this examination of the fresh tissues gives no result, small fragments of the same tissues are fixed for two to four hours in Zenker's solution (Potassium bichromate 2½ parts, corrosive sublimate 5 parts, water 100 parts, and acetic acid 5 parts). They are then washed for some minutes in water, and teased out upon a slide. The discovery of Negri's bodies is more easy in tissues treated in this manner than in fresh tissues.

3. When necessary (which very rarely happens) sections are cut, and stained by the rather complicated technique of Mann.

Negri's corpuscles are only visible after a sufficiently long period of incubation. Their appearance coincides with that of the first symptoms of the disease. They resist putrefaction, and are preserved in glycerine. In cases of furious rabies, they are found especially in Ammon's horn.

Sinigaglia has described bodies resembling Negri's corpuscles in the cells of the conjunctiva, bronchial epithelium, and nervous centres of dogs suffering from distemper. The distemper is localised in the regions in which these corpuscles of Sinigaglia are found. Negri's corpuscles can be differentiated from Sinigaglia's by the following characters.

Negri's bodies are distinct and regular in outline. The outline of Sinigaglia's bodies is distinct, but is irregular, undulating, and sometimes tortuous.

Negri's bodies contain internal formations which are well individualised, unequal, and often budding. Sinigaglia's bodies contain internal formations which are smaller than those found in Negri's bodies, are equal, and have a granular appearance *en masse*.

Each cell contains one or several of Negri's bodies. The number of cells containing Sinigaglia's bodies is very small.

The author, from numerous examinations, is convinced that to examine for Negri bodies is a reliable method in the diagnosis of rabies.—(*Annales de Méd. Vét.*)

MAGNESIUM SULPHATE AS AN ANTIDOTE TO ARSENICAL POISONING.

D. Sieber states (*Bulletin de Sciences Pharmacologiques*) that a hypodermic injection of magnesium sulphate, in a dose representing half a gramme of the drug per kilogramme of the animal's body-weight (roughly 7.7 grains to 2.2 lbs.) is capable of saving a rabbit which has received an ordinary lethal dose of arsenic by the mouth or under the skin, but not if the arsenic has been given intravenously. The magnesium sulphate therefore only acts as an antidote to arsenic so far as the latter drug has not yet invaded the circulation.

The author's view of the mechanism of the antidotal action of magnesium sulphate is that it consists in a retardation of absorption by the formation of a chemical combination which is deficient in solubility.—(*Annales de Méd. Vét.*)

W. R. C.

CENTRAL CANADA VETERINARY ASSOCIATION.

The eleventh annual meeting was held in the Board of Trade Building, Ottawa, on Jan. 23rd. Meeting called to order by the President at 7.30 p.m. for business and papers. About 35 members were present.

Under the heading of new business it was moved and carried that the sum of five guineas be forwarded from this Association to the Hon. Sec. and Treasurer of the Hunting Memorial Fund, London, England, to assist in affording a suitable recognition of the life work of the late Mr. William Hunting.

An authorised schedule of fees was approved and instructions given to the Secretary to have a certain number printed, as follows:—

First visit in City or Corporation	dols. 2.00
Subsequent visits to same case	1.00
Dentistry: Dressing or floating teeth at	
Infirmary	1.00
Extraction of molar teeth	from 3.00
Cutting of molar teeth	" 3.00
Parturient apoplexy	" 5.00
Castration of colts	" 3.00
Parturition	" 5.00
Removal of retained placenta	" 3.00
Prolapsus uteri	" 5.00
Anæsthetics—horses and cows	" 5.00
Visits: First five miles outside town or city	
limits	per mile 1.00
Each subsequent mile	" .50
Examination for soundness with certificate, from	3.00
Double fees and mileage charged for calls	
from 7 p.m. to 7 a.m.	
Detention fees:	
During day, after first hour	per hour 1.00
During night, after first hour	" 1.50
Consultations	" from 3.00
Consultations at surgery	" 1.00

Papers read and discussed occupied considerable time. The paper on Contagious Abortion was received with interest. This paper dealt with the isolation of Bang's bacillus and the presence of the organism in the dairy milk. This paper was read by Mr. Charles Evans, Department of Agriculture.

The most important paper on Surgery was one by Mr. Geo. Hilton on "The Operation for double Scrotal Hernia in the Horse."

The meeting further instructed the Secretary to frame up a resolution from this meeting to the Hon. the Minister of Agriculture urging the Government to take steps towards forming regulations for the control of bovine tuberculosis.

Officers elected for the ensuing year were as follows :

Hon. President.—Dr. Fred Torrance, The Veterinary Director-General.

President.—Mr. Geo. Hilton.

Vice-president.—Mr. R. T. O'Hara.

Hon. Secretary-Treasurer.—Mr. T. C. Evans.

Executive Council.—Messrs. W. G. Austin, A. E. James, J. B. Hollingsworth, H. D. Sparks, and W. C. McGuire.

Auditors.—Messrs. A. W. Harris and Young.

CHARLES EVANS, Hon. Sec.-Treas.

8 Hartington Place,
Ottawa, Canada.

THE NATIONAL VETERINARY BENEVOLENT AND MUTUAL DEFENCE SOCIETY.

The annual meeting was held at the Grand Hotel, Manchester, on Thursday, 5th March, at 4.30 p.m. The President, W. A. Taylor, Esq., Manchester, in the chair. There were also present Messrs. Wolstenholme, Sumner, Stent, Munro, Lindsay, Spreull, Pillers, Hopkin, McKinna, Clarkson, and G. H. Locke, hon. sec.

Apologies for absence were received from Messrs. Carter, Shipley, J. H. Wright, Trigger, Elam, Abson, Dawes, Packman, Jackson Young, Woods, J. S. Lloyd, Wharam, and A. W. Mason.

The minutes of the last annual meeting having been published, were taken as read. Proposed by Mr. Stent, seconded by Mr. Sumner.

PRESIDENT'S ADDRESS.

The PRESIDENT, in his address, said : It is with great pleasure that I rise to address you, in accordance with Rule 4, at the annual meeting of this most useful Association. I do not intend to do more than reiterate the remarks that I made at the last annual meeting. You will remember the matters alluded to on that occasion, which have been issued in pamphlet form and circulated to all the members of the Society, and also to every member of the veterinary profession.

So far as the Defence Branch of the Society is concerned, I think only two cases have had to be considered by the Council, and one at present is still under consideration.

The Benevolent Branch is something like the poor, always with us, and there is constant disbursement of our funds taking place throughout the year. I think we are at the present time expending all that we are empowered by the rules to dispose of, at least there or thereabouts.

I am informed by our worthy Secretary that the membership stands somewhat better than last year, but it is not for me to trench upon his report.

I cannot understand why more members of the profession do not join this Society, and I think it is a matter of amazement to the Council of this Society. Of all the Associations that exist in connection with our

profession I look upon this Society, in the case of a young man starting a practice, as the most valuable one he could join. If he could not afford to join any other Association he should join this one. It is useful not only in connection with cases taken into the law courts, but in other cases where threatened action calls for prompt procedure. I have heard of men subscribing to ordinary insurance societies to cover their liabilities, but how much better would it be to come to a Society like this where they can have the benefit of the experience and the assistance of the officers and the Council.

I do not intend to occupy your time further, and will ask the Secretary to give you his report.

HON. SECRETARY'S REPORT.

Mr. LOCKE reported as follows : I am pleased to say the Society is still progressing, but rather slowly. We had at the end of the year 275 members, there were 15 new members and seven resignations. This year, since January, six new members have joined. Three members have died this year.

We have now about 10 recipients of our benevolence, and two grants of money were made. We have lost three good friends by the death of Mr. Faulkner and Mr. Hunting, and through the resignation, on account of ill-health, of Mr. Butters. Their places on the Council require to be filled.

There has been a change in the trusteeship, and in place of Mr. Faulkner, Mr. Packman, of Bury, has been appointed. There are two changes in the Life Governors of the Benevolent Branch. The Midland Society have adopted Mr. Dawes, and I have been adopted to represent the Lancashire Society.

Two donations were received, one of £5 5s. and another of £2 2s.

In the Defence section we have had two cases, one of which was won at a cost of £15 16s. 3d., and the other is in abeyance.

TREASURER'S REPORT.

Mr. WOLSTENHOLME said the balance sheet had been printed and distributed to every member. It speaks for itself.

In interest alone, *plus* the donation of Mr. Sewell, we have received £196 12s. 3d., sufficient for all purposes without touching capital, which is excellent. We have disbursed £162 12s. I am sorry to say there is a sum of £29 8s. owing from members in arrear with subscriptions, some members being as much as five years behind. I think their names should be deleted from our list.

Mr. HOPKIN, in opening a discussion, referred to the President's remark—that in the Benevolent Branch the expenditure had nearly reached the limit, but so far as he (Mr. Hopkin) remembered, they were not bound to a specified amount.

Mr. WOLSTENHOLME replied that only the interest from the money invested by the Benevolent Fund could be expended.

Mr. LOCKE read Rule 10 as follows :—"The present capital of the Fund, and all monies received whether donations, subscriptions, or legacies, shall be invested, and only the interest or usufruct, or a part thereof, which may be received therefrom, is to be expended."

Mr. HOPKIN asked whether any surplus in the amount expended out of the interest in one year could be expended in the following year.

Mr. WOLSTENHOLME replied in the negative, and said unused interest in any year passed into the capital account.

Mr. CLARKSON thought it a pity that these balances should have to be re-invested, and the rule should be altered. According to the present rule there is nothing in hand to spend at the beginning of a year.

The TREASURER said there was always loose money in the bank in the name of the Benevolent Fund which could be used.

Mr. HOPKIN considered that times had changed so much, the Society was prosperous, and more money should be disbursed; and after further discussion he gave notice that he would propose an alteration to Rule 10.

Mr. MCKINNA moved a vote of thanks to the retiring officers, especially mentioning the President, Secretary, and Treasurer. He echoed the words of the President in saying it was lamentable that out of three or four thousand members of the profession only about 274 avail themselves of the benefits of this Society. The first thing he did was to join, and although he had never had to claim its help he felt that he was doing something towards the benevolent branch.

Mr. LINDSAY seconded, and it was heartily carried.

The PRESIDENT thanked the proposer and seconder on behalf of his co-labourers and himself. When coming to the meeting he asked himself which member of the executive, excluding himself, had the hardest work, and said it lay between the Secretary and Treasurer. He came to the conclusion that during the past year it was the Treasurer. The trio had, however, pulled together and worked as one man.

The PRESIDENT then vacated the chair.

Mr. HOPKIN, in proposing that Mr. TAYLOR be re-elected President, said he remembered many years ago proposing Mr. Taylor's father for the same position, which he occupied to the close of his life. The son had done the work so ably, and followed in the footsteps of his father; he possessed the attributes necessary for the position, and had the interests of the profession at heart that they could do no other than ask him to again resume his position in the chair.

Mr. MCKINNA expressed great pleasure in seconding.

Mr. TAYLOR again took the chair, and said that so long as he had the power, his services would be at the disposal of the Association.

Vice-President. Mr. WOODS was proposed for re-election by Mr. Sumner, seconded by Mr. Wolstenholme. Carried.

Council. Mr. NOËL PILLERS moved that the Council be re-elected with the substitution of the names of Mr. Lindsay, Dumfries, and Mr. Slocock, Hounslow, for those of Mr. Faulkner, deceased, and Mr. Butters resigned. Mr. Spreull seconded. Carried.

Mr. LINDSAY was gratified with his election, and said he would endeavour to further the interests of the Association to the best of his ability.

Treasurer. Before being re-elected, on the proposal of Mr. Hopkin, seconded by Mr. Munro, Mr. Wolstenholme desired the meeting to know that at the end of this year he felt that he would have to relinquish the post. When first elected it was a revelation to come into close contact with the brave hearted founders of the Society.

Hon. Secretary. Mr. Sumner said there could be little difficulty in selecting the man for this post. They knew the breed of Mr. Locke, and his capacity for the work. This had always given entire satisfaction. He proposed Mr. Locke. Mr. Lindsay seconded. Carried.

Auditors. Mr. J. H. Wright, M.R.C.V.S., Manchester, and Messrs. Litton, Pownall and Co., were re-elected on the proposition of Mr. Stent, seconded by Mr. Clarkson.

The question of the action to be taken in regard to members in arrear was discussed. Mr. McKinna proposed that a registered letter be sent to those members whose subscriptions are over two years in arrear, drawing their attention to rule 2. Mr. Hopkins seconded, and it was approved.

WILLIAM HUNTING MEMORIAL.

The PRESIDENT: You are all cognisant of the fact that most of the veterinary societies have been approached by those responsible for getting up a memorial to the late Mr. William Hunting. Mr. Hunting was a member of this Society, and a man whose loss the members most deeply deplore. During his lifetime no action was taken by Government to indicate the esteem in which he was held by the members of our profession and which some of us thought he richly deserved. No recognition of a public nature was taken with regard to Mr. Hunting's indefatigable work in connection with public health, sanitation, and other matters relating to some of the diseases communicable from animals to man. The question is whether our Society in reply to the application can take action in the matter in the way of making a presentation to the Memorial Fund. Personally, I can find no rule which will empower us to do so. This Society was formed for the defence of veterinary surgeons in case of unjust claims and actions at law which might be brought against any of its members. It was also framed for benevolent purposes, and we can hardly look upon a public memorial though it be a professional one as a fit object upon which to expend the funds of our Society. The memorial is not taking the nature of a charitable investment, otherwise probably our Society might be within its rights in allocating a subscription to the fund. [No action was taken in the matter].

It was resolved that a report of the annual meeting be printed and sent to each member of the Society.

The meeting closed with a vote of thanks to the President.

G. H. LOCKE, Hon. Sec.

The Relation between the Bovinoid Tubercle Bacilli found in Man and True Bovine Tubercle Bacilli.

Mr. Walter H. Fearis, Department of Bacteriology, King's College, writing to *The British Medical Journal*, says:—"In the first place, it must be noted that although some investigators—for example, the British Royal Commission, Frazer, Philp Mitchell, Raw, Weber—have found bacilli of bovine type in tuberculous children, such evidence is no proof that the children were infected by tuberculous cattle: the source of infection may have been other human beings infected with tubercle bacilli of a similar bovine type. Working quite independently of the writer, Ralph Vincent also has arrived at this conclusion.

Secondly, it has not yet been proved how many—if any at all—of the tubercle bacilli of bovine type found in the tuberculous children were really identical with the true bovine tubercle bacilli of cattle. It must be remembered that, up to the present, the assumption of this identity has been based on evidence obtained by very careful cultural observations, and the study of the pathogenic effects produced by each of the two kinds of bacilli on animals alone but not on man. All the reliable evidence so far obtained from observations of the effects of the bacilli on man strongly suggests that the true bovine tubercle bacillus is not strictly identical with the bacillus of bovine type found in tuberculous human beings. Thus, by inoculations made on himself, Carl Spengler demonstrated that whereas the true bovine bacilli are relatively harmless to man, on the other hand, the bacilli of bovine type found in human beings are exceedingly virulent and capable of causing extremely severe toxic symptoms—indeed, the latter type nearly caused death. Spengler's observations are confirmed by similar investigations made by v. Baum-

garten and Klemperer, who likewise demonstrated the relative harmlessness of the true bovine tubercle bacillus to human beings; the investigations of the Italian and Japanese Governments carried out under the direction of Gosio and Kitasato, respectively, are additional confirmation; further important evidence which harmonises with Spengler's conclusions is to be found in the researches carried out by Koch, Kossel, Möllers, Weber, Emmett Holt (of New York), Ungermann, and Burnet, amongst many others.

Spengler has especially studied the tubercle bacillus of bovine type found in man; he calls this bacillus *Typus humano-longus*. Under certain conditions the virulence of *humano-longus* is greatly diminished; this would partly account for the mild course of the disease seen in so many cervical gland, bone and joint cases in children. Further, it is very probable that the true bovine bacillus plays an important part in immunising children against *humano-longus*, just as the virus of vaccinia immunises so well against variola. Indeed, from the results of his researches and other evidence, Spengler has advanced the hypothesis that the true bovine tubercle bacillus may be regarded as a jennetised *humano-longus*, the latter, by animal-passage on cattle, having lost its severe pathogenic action towards man, thereby becoming changed into the relatively harmless true bovine tubercle bacillus. In his admirable communication on the subject, Clive Riviere has also alluded to the probable immunising action of the true bovine bacillus on man under the ordinary conditions of life.

Since morphological and cultural tests, and animal investigations, do not appear to be capable of helping us to distinguish a relatively harmless true bovine bacillus from a *humano-longus* which is highly dangerous to man, therefore a laboratory method for distinguishing between the two is urgently needed.

Possibly, in the recent ultra-microscopic researches carried out by Spengler on the toxins of the tubercle bacilli, some solution of the problem may be found. In this communication only a few interesting points can be touched on concerning these investigations. Bouillon pure cultures of the tubercle bacilli to be tested are prepared. The emulsified surface-growth on each flask of bouillon is well shaken with the liquid in the flask, and, after standing, the contents are filtered. The filtrate—the "toxin"—is diluted to a strength of 1 in 10 with saline, and then examined in an ultra-microscope arranged for investigations on colloids. The following have been observed:

Type of Tubercle Bacillus from which the Toxin was Obtained.	Colour of the Cone of Light Observed in the Ultra-Microscope.
<i>Typus humanus brevis</i> , Koch.	Grass green.
<i>Typus humano-longus</i> , Spengler. (The tubercle bacillus of bovine type cultivated from human beings.)	Greenish-blue.
True bovine tubercle bacillus isolated from cattle.	Soft blue (N.B.—No trace of green).

In those toxins which I have examined there has been no difficulty in distinguishing between the soft blue light obtained with the toxin of true bovine bacilli and the distinctly greenish-blue light characteristic of the toxin of *humano-longus*.

Obviously, it is urgently necessary to repeat these observations, using tubercle bacilli of bovine type ob-

tained from a very large number of tuberculous human beings resident in many different districts and countries.

Thus it will be seen that a great deal more work remains to be accomplished before we shall be in a position to state that the tubercle bacilli of bovine type found in tuberculous human beings have been communicated from tuberculous cattle to man. Some cases may be found to be due to cattle, but, in order to prove this, the necessary evidence must be obtained.

In the meantime it is extremely desirable that every effort should be made to ensure a clean and pure milk supply. Amongst others, Lord Rayleigh, Sir John Byers, and Mr. Robert Mond have shown how this can be accomplished in a practical manner."

Disputed Sale of a Hunter—Claim by a Veterinary Surgeon.

At York County Court on Tuesday, 10th inst., before his Honour Judge F. G. Templer, Alexander Farquharson Durkie, of Mill of Mains, Dundee, farmer, was the plaintiff in a case which had been remitted from the High Court. Plaintiff claimed the sum of £80, the price of a horse sold by him to Rowland Francis Meyrick and Eleanor Meyrick, of Hall Orchards, Wetherby, on May 23rd, 1913. There was a counter-claim for £12 17s. 6d., for the difference in the price realised for the sale of the horse, stabling, etc., and veterinary fee.

Mr. Harry Wray, of Hull, in opening the case, said that both parties had conferred and agreed that it was a case which should come before his Honour for trial, because of the convenience of the parties who had travelled from Dundee. York was the nearest point to the defendants' residence.

Plaintiff lived near Dundee and bred animals. He was not a professional horse dealer but a Justice of the Peace and a County Councillor. The horse in dispute was, in the first instance, described as sound and quiet. A letter of May 22nd by Mrs. Meyrick to the plaintiff said that her husband would buy the horse at £80, and he would be pleased to have it "vetted" first. That, he suggested, constituted a bargain. The horse was duly delivered to the defendant's home. When despatched it was in perfectly sound condition.

Mr. N. Crombie, of York, for the defendants, said his case was that the horse was not sound, and suffered from malformation of the hocks. It was represented as sound, and he therefore alleged breach of warranty.

Mrs. Meyrick stated that she arranged to purchase the animal from Mr. Durkie on the representation that it was clean, sound, and quiet. Immediately the horse arrived it was examined by a veterinary surgeon. Her husband did not like the animal, and it was returned as unsound and suffering from "curb" bone. The agreement when the horse was purchased was that it should be sound and quite fit for hunting purposes, for which it was required.

By Mr. Wray: Witness said she purchased the animal. Her husband was opposed to her buying the horse. Subsequently she wrote stating that her husband would buy the horse for £80, at the same time asking for it to be "vetted." She further asked if it was sound. She could not now state that when she first saw the horse it had two "curbs," but certainly there was one. Although at first she wrote stating that she was disgusted, she yet expressed her wish to see it again.

In answer to his Honour, Mr. Wray said his client did not sell the horse on a warranty.

Mrs. Meyrick's evidence was corroborated by three veterinary surgeons from Leeds, Messrs. G. E. Bowman, A. W. Mason, and Samuel Wharam; and by Mr. Meyrick, all of whom spoke to the animal having a

"curb" when seen and examined by them, and which, in their opinion, must have been of considerable standing, and could not have been "sprung" on the railway journey or whilst in Mrs. Meyrick's possession.

Plaintiff said he bred the horse in question; it was by Akbar, a super-premium horse. During the time the horse was in his possession it had never been treated for faulty hocks. He himself was a Member of the Royal College of Veterinary Surgeons, and had lectured at Aberdeen University. The animal was good when it left his place at Dundee, but when he saw it again at York, he was certain that it had been "treated." There was no malformation of either hocks. It had highly developed bones, which would give it more strength.

By Mr. Crombie: When he bought the horse back he found out the state of the hocks, and was certain it had been "treated." Mr. W. Hunting had not told him that the animal was unsound. Mr. Hunting had since died. "Sound and quiet" was a proper description of the animal. There were many forms of malformation.

Mr. Crombie: It is said that people breed for profit, but you say you do not.

Witness: Well, I do not.

Alexander Frederick Durkie, surveyor, son of the plaintiff, said he had ridden the horse in question. Witness knew the horse from birth. It had never had a "curb" whilst in his father's possession, and had never been blistered. The horse had always been healthy and had never been "sick or sorry" for one day. Witness travelled with the horse. It did not suffer from a "curb."

Andrew Spreull senior, partner of Messrs. Spreull and Sons, veterinary surgeons, stated that in May last he saw the horse in question. He submitted it to a very close and searching examination, and gave a certificate that it was perfectly sound. At that time there was not a "curb" on either hock, nor was there any sign of the hocks having been treated. At the time of his examination there was no fulness or malformation of the hocks. The bones were largely developed. Witness saw the horse after its re-sale, and the condition of the hocks then was due to it having been in the railway truck. The large bone of the hock had a tendency to strengthen the legs, rather than to weaken them. Witness asserted that in answer to a letter since the examination he stated that the hocks were sickle shaped.

John Duncan, coachman to Mrs. Ogilvie, sister to Mrs. Meyrick, said the horse was quite in good condition when he saw it in August.

Thomas Matthew Inglis, M.R.C.V.S., of Forfar, veterinary surgeon to the Board of Agriculture, said that on March 2nd last he examined the horse in question. He found both hocks sound. His opinion was that "once a curb always a curb." The bones were prominent, but this was not malformation. It was a common thing to be found in blood horses, and did not affect the soundness of the animal.

John James Ridley, M.R.C.V.S., veterinary surgeon to the East Riding Yeomanry, gave similar evidence to the last witness. He examined the horse on June 10th.

James G. Dean, M.R.C.V.S., Bishop Auckland, also gave similar evidence.

Mr. Harry Wray, in addressing His Honour, contended that the horse was fit and well when it was delivered. This was borne out by the certificate of soundness that was obtained prior to its despatch. He would not suggest for one moment that anything wrong had been wilfully done to the animal.

His Honour intimated that he did not wish to hear Mr. Crombie in reply.

JUDGMENT

His Honour, in giving his decision, said it was one of those cases in which there had been a misunderstanding

between the parties, and one that it was very difficult to decide. It would have been better if Mr. Wray had had a jury. It was, he thought, unfortunate that the case should have been imposed upon him (the Judge). It should have been tried in Dundee. With respect to the witnesses on either side, he said there was a direct conflict of evidence. After carefully reviewing the evidence, he found for the defendant on the claim and on the counter claim, with special costs.—*The Yorkshire Herald*.

The Cambridge Field Laboratory.

Under the direction of several of the University professors a field laboratory has been started about a mile outside the town of Cambridge. It is arranged on entirely new lines, and is designed to bring together into close association the subjects of agriculture, biology, and pathology—or, in other words, veterinary science and medicine.

The work on tropical diseases has shown that certain of the larger animals act—as in the case of the big game in Africa—as reservoirs of poison. Veterinary science in the tropics has therefore become a part of medicine. even as medicine has become a part of veterinary science.

In this country we have such plagues as swine fever, foot-and-mouth disease, and redwater fever, all of which may have distinct bearing on human ailments; bovine tuberculosis, which in the view of many investigators does have such a bearing; typhus fever, which has been proved to be connected with body parasites; anthrax, actinomycosis, and some others.

In these circumstances the need for study along converging lines is obvious. At Cambridge every effort is made to keep the various departments in close touch. The farm is built round a central administration block of buildings, and though each department has a separate laboratory every facility is afforded for interchange of ideas. In the biological department some highly important investigations on tick-propagated diseases are being carried out by a very great authority on this subject which affects rabbits, cattle, and deer, and in Africa as East Coast Fever, which affects, amongst other animals, cattle, horses, and dogs.

There is a large collection of animals at the field hospital, including dogs, cows, a "salted" or infected horse from the Transvaal, and a jackal. It has been shown that the tick diseases of most animals are peculiar to them and cannot be transmitted from one species to another. It has also been demonstrated how enormous are the difficulties to be faced in preventing spread from infected to clean herds.

An illustration of the voracity of these insects is exhibited in a snake upon the neck of which a tick has fixed itself. Apart from the disease which they carry, the ticks may occur in such swarms that animals are bled to death by them—as occurred some years ago in a deer park in Cornwall.

The agricultural side of this work is being developed in connection with various dips which may be relied upon to kill the ticks. Dipping troughs are a feature of the farm, and experiments are at present being carried out with preparations of arsenic.

To a question, "Why do you work so much on diseases connected with hot climates?" one of the investigators replied, "Because we can get funds for tropical work. Money for home disease work is simply not forthcoming, and we have to be exceedingly careful, since these experiments cost a great deal."

Next to the biological section is the section devoted to pathology. Here a well-known investigator conducts a series of experiments on lupus, and has already succeeded in showing that when inoculated into animals

this disease produces a true tuberculosis. Lupus is often of bovine origin and may be caught from milk. Very strong evidence in favour of the idea that tuberculous milk is a highly dangerous commodity has been produced. Attempts are now being made to obtain a vaccine which shall confer immunity from the disease upon a number of monkeys.

Experiments are also being conducted upon the question of fecundity, and a South American drug, Yohimbin, is being extensively tested.

The field laboratory contains an operating theatre, where surgical operations are carried out upon some of the smaller animals, like dogs, goats, and calves. A beautifully-fitted post-mortem room completes the equipment of the farm.—*The Times*.

The Horse Owner and the Motor.

In a paper read by Mr. J. Gibbins at the annual meetings of the National Union of Horse and Vehicle Owners, and from which the following excerpts are taken, an attempt is made to forecast the immediate future of the question of the use of horse traction:—

"The profitable nature of a change from horse traffic to motor traffic depends upon the volume of horse traffic displaced, the relative cost of each, and the volume of traffic to be gained; in other words, what work can be guaranteed your horses, what are the receipts per mile covered, what is the cost per mile, and what are the corresponding costs for motors.

It must always be borne in mind that the situation will probably change from time to time, and that the horseowner, who has also become a motor owner, may find that his former anticipations with regard to the maintenance of his horse traffic have been too optimistic.

In the paper I had the honour of reading before you two years ago at Manchester, one opinion I gave was that the horse had an advantage in cases where the work to be done consisted of a small mileage, or light loads, and lengthy periods of waiting. In so far as it affects the horse hire contractor, I consider that while the proposition is perfectly true to-day, a great change has occurred even during the last two years. There are several things which have operated in favour of the introduction of motor vehicles to replace horses, quite apart either from first cost or the cost of running and maintaining.

One is that a business man nowadays dislikes the term "old-fashioned." He believes, as he says, in going with the times. The more conservative of tradesmen hang back until they feel that they have to go with the swim, and, although perhaps with reluctance, the first experiment is taken simply because a competitor has already taken the plunge.

It is also a fact that the increased expenses thus incurred are often justified by an increase of trade secured by the quicker and more frequent deliveries, by the advertising value of the motor vehicle, and, what is perhaps of most importance, the much greater distance and area covered in one day.

The motor char-a-banc and motor cab introduced by a proprietor has the effect of causing his neighbour to think he is getting left behind. The result may be good or it may be bad for either or both. The new method will inevitably compete against the older, and when both horse vehicles and motor vehicles are run by one firm the proprietor must make up his mind, so far as his horses are concerned, to suffer the competition not only of his neighbouring motor proprietor, but also of himself. He must, therefore, like the tradesman, consider whether the new traffic he obtains from the

employment of motors is enough to compensate him for either the entire loss of his horse traffic receipts, or for the partial transfer of his own motor vehicles. He must also consider the percentage of costs compared with the receipts in each case.

Another branch of hiring also may be alluded to. Although motor funerals are not common occurrences, quite a considerable number of so-called motor hearses are now being employed both in London and the provinces. A motor conveyance to convey bodies long distances is an adjunct to the business of a funeral carriage master, possessing its advantages; and if the use of it is confined to competing with the railway companies this innovation has not the fault of competing with the horse. But here, again, there is a strong probability that competition will step in against the horse-owner in time, and that a purely motor business will also seek to enter into this class of traffic, and not possessing the stock of horse vehicles will have no compunction in creating a fashion for the employment of motor *laudau-lettres* to take the place of funeral broughams.

The problem of the horse supply is bound up with its profitable use, and it is undoubtedly a national problem, because of its use in agriculture, in the Army, and under many conditions in commerce. Being a national problem, it is necessary for unfair restrictions to be removed, and the incidence of taxation adjusted, so that the burden is lifted from the shoulders of the horse owners.

I have not touched upon the heavy horse traffic and its relation to motor developments. There has, however, been a rapid development during the last twelve months; brewers, millers, furniture removers, and manufacturers of all kinds who formerly looked askance at the petrol or steam lorry, are now buying them freely, and the owners of heavy horses will know better than I do what effect this has had upon their business, and in what manner it is being met. It must not be forgotten that the success of the motor car during the last five years has been greatly accelerated by the great prosperity the country has enjoyed. Good judges are of the opinion that the tide of prosperity is receding. When the slump does occur, the receipts of the owners of motor vehicles will be materially affected, and the value and the economy of motors employed as a trade accessory will be considerably less on a reduced turnover. In the past the carriage master and the carting contractor have been among the first to feel the effects of bad trade, and the motor proprietor and motor builder will also come in to bear the first pinches of adversity.—*The World's Carriers*.

The Zigaya Sheep.

A bulletin from the International Institute of Agriculture describes the Zigaya sheep. The predominant breed for the production of wool in the south-east of Europe, and particularly in the Balkan countries, it is also bred for meat and milk. The wool of the thoroughbred is pure white, and at one time extensively exported to Western Europe. Pure breeding has been much neglected, and most of the wool is grey or streaked with black. At one of the State breeding establishments in Hungary the average live weight of rams two years old is 94½ lb., of ewes in milk 77 lb. to 86 lb., old rams may reach 132 lb. to 143 lb., and old ewes 97 lb. to 110 lb. The rams are almost always horned, and the ewes hornless. This sheep has a small head, with a tapering muzzle, face and legs are usually covered with stiff black hairs. The horns of rams are ringed and curved in a spiral. Cross-breeding to improve wool or yield of milk or meat has been practised to a limited extent.—*Live Stock Journal*.

 NOTE.—The figures for the Current Year are approximate only * As Diseased or Exposed to Infection

Edinburgh Milk Supply.

At the annual dinner of the Royal (Dick) Veterinary College held recently Professor Gofton, in proposing the toast of "The City of Edinburgh," referred to the question of tuberculosis and its treatment and preventions in the city. They knew, he said, that the city, so far as the treatment of tuberculosis in human beings was concerned, occupied the first place certainly in Great Britain. But there was another aspect of the tuberculosis question, in which the city was certainly behind the times. The attention of the city and its inhabitants must have been very strikingly drawn to the question of the prevention of tuberculosis from animal sources within the last few weeks by the publication in the daily Press of facts which were known to those, at all events, who had been in touch with the various workers some time before. It appeared that, roughly speaking, about 15 per cent. of their milk supply contained living tubercle, and that compared with other cities Edinburgh was twice as bad as the average of the cities in the United Kingdom. If that was the case, it indicated clearly that the city had room for advancement and progress. Edinburgh had been the first city in the United Kingdom to have a veterinary staff to carry out meat inspection, but it seemed to him that the city had not quite kept the pace in other respects in connection with tuberculosis.

Councillor Young, in reply, said the question of the milk supply and the question of meat inspection were under consideration at the present time by the Committee over which he presided. He had made inquiries as to the method of inspection adopted with regard to the milk which came into the city of Edinburgh. He was informed that periodically a large number of samples were taken of all the milk that was brought into the city, and carefully tested at the Usher Institute of Public Health. He saw Professor Hunter Stewart, the head of the Institute, who informed him that all the samples received up to date had given negative results, with some two exceptions. If the system of sampling was satisfactory, then we would be compelled to turn attention to the milk which was produced. There he found that all the cows in the city, some two thousand of them, were inspected by a veterinary inspector once in four weeks at the outside, and that the milk in Edinburgh ought to be as germ free as it was possible to be. But the milk which was sold in the shops was not as satisfactory as it ought to be, and the Public

Health Committee were determined to find out how that could be remedied. The city of Edinburgh possessed certain powers which seemed to him quite unsatisfactory. If an inspector found a cow that he had reason to believe was tubercular, all he could do was to order the cow's removal, and the animal was traded off into some part of the country where veterinary inspection was not so close as in the large cities. It seemed to him that they not only wanted perhaps better administration in the city, but they wanted legislation to get at the root of the whole matter, and enable them to stamp out tuberculosis in cattle. That was one of the great tasks which lay before the veterinary profession.

Regeneration of the Testis.

Mr. C. J. BOND has recently published the results of some interesting experiments on the effects of orchectomy in birds (*Journ. Genetics*, 1913, iii, 131). In a paper which appeared in the *B. M. J.* July 21, 1906, Mr. Bond showed, among other results, that the removal of one ovary in the rabbit is followed by compensatory overgrowth of the remaining ovary. While investigating the question whether a similar compensatory hypertrophy occurred in the case of removal of one testis, the author was led to the interesting discovery that after apparently complete intracapsular removal of a testis, regeneration of the secreting tissue and tubuli seminiferi occurred *in situ*. It is of interest to note that this result only applies to birds, no evidence of any similar intracapsular regeneration having been obtained in mammals. Mr. Bond points out that "the domestic fowl has undergone a process of artificial selection in regard to the egg laying capacity of the female sex gland, and probably also in regard to the sperm-forming capacity of the male gland, hence it is of interest to find that the testis of the domestic fowl has great powers of structural and functional regeneration after partial removal, greater apparently than exists in mammals." It is naturally a point of great interest to determine whether, from the gametic standpoint, the regenerated sex gland differed from the previously existing structure. To test this Mr. Bond crossed the same female with a male before and after orchectomy. The experiment performed on fowls revealed no difference between the offspring before and after operation on the male parent. In the case of two experiments on pigeons some differences of a fairly definite character were noted,—*Brit. Med. J. nrl*;

Helminths and Cancer.

In a memoir recently published, Dr. Johannes Fibiger brings forward strong evidence in support of the view, by no means novel, that the lesions of the tissues produced by parasitic worms may act as the starting-point for the development of cancerous growths and tumours, the author found in wild rats a disease of the oesophagus and stomach characterised by an epithelial proliferation and inflammation leading, in pronounced cases, to a papillomatous growth which was the precursor of a malignant epithelioma. Examination of the primary lesions revealed the presence of a nematode worm, an undescribed species of spiroptera.

From a series of experiments it was concluded that cockroaches (*Periplaneta americana* and *P. orientalis*) serve as intermediate hosts for the spiroptera. The cockroach becomes infected by ingesting eggs of the worm which are passed out in the excrement of the rat; the eggs develop in the cockroach and the embryos of the worm become localised in the striated muscles of the prothorax and the legs. The rats become infected by eating cockroaches, and the embryos of the worm, set free from their cysts, attack the epithelium of the stomach, sometimes also that of the oesophagus or buccal cavity, and develop into the adult nematode, the cause of the lesions already mentioned. From his investigations the author concludes that all anatomical alterations are due to toxic products of the nematode. From the primary lesions caused by the nematode secondary metastases may be produced in other organs. The metastases contain neither the parasite nor their eggs. The development of the metastases is ascribed to the faculty of the epithelial cells to multiply in other organs independently of the parasite. The author thus confirms the view put forward by Borrel and others that nematodes may produce malignant tumours in rats and mice, and considers it not improbable that in human pathology also cancerous tumours may owe their origin in some cases to the presence of helminths.

Foot-and-Mouth—A Lesson from the Past.

A correspondent to *The Scotsman* writes:—

"In view of the present outbreaks of foot-and-mouth disease in England and Ireland, and the outcry in some quarters against the restrictions imposed, the recollections of an incident in a former outbreak in the 'seventies' may not be out of place.

The gentleman who relates these particulars was at that time in charge of the sheep stock of an extensive holding in the South of Scotland, when the ewe stock numbered sixty-eight scores, and the lambing time had just commenced when the fell disease made its appearance. "It was," says this veteran, "the worst business I ever tackled. The ulcerated condition of the mouth and of the feet, led to many ewes going off their food, and off their feet, and lambs were unable to suck, partly because of the sores on their mouths, and partly because their dams refused to rise. Many of the ewes that were infected before lambing did not survive, but with very few exceptions those that had lambed before infection came safely through the trouble. The death-rate was very heavy, and when the flock was again sound there was found to be a shortage of nearly thirty score of lambs, and among the remainder were many that fell far below the usual quality and condition. In addition, quite a number of the ewes suffered constitutionally, so that they could not be retained in the flock, and had to be cast as shots."

Those who have not known such trials are apt to minimise the consequences of an outbreak, and are inclined to cry out against restrictions imposed with a view to

preventing the spread of the disease. But surely it is infinitely better to suffer some little hardship and privation rather than run the risk of introducing such a disease at the present critical time when lambing is just commencing. In this instance surely the first loss is the least, and any slackening of the regulations can only be playing with fire.

Addresses Wanted.

The following list of names appears in the recently published Register of Veterinary Surgeons:—

Name.	Last address known.
Bell, E. W.,	53 Jeffreys Road, Clapham, S.W.
Blakely, John,	Elm Street, Rye, New York, U.S.A.
Blane, W. T.,	Castle Donington, near Derby.
Boase, J. T.,	Cotswold Chambers, Church Square, Cape Town, South Africa.
Cakebread, W.,	De Burgh House, Fairholt Road, Stamford Hill, N.
Dowdall, Arthur,	Stafford Street, Longton, Staffs.
Duff, James A.,	Glen Arthur, Duddingston, near Edinburgh.
Garrett, Richard,	Tubercurry, Co. Sligo.
Gorman, James,	24 Major Street, College, Toronto, Ontario, Canada.
Goundry, Charles,	G.V.S., Malmesbury, S. Africa.
Houston, David Spiers,	Westvale House, Port Glasgow.
Kelly, Vety.-Capt. Edward Harvey,	late A.V.D.
Ledger, Wm.,	Chicago, Illinois, U.S.A.
McLeod, J.,	Christchurch, New Zealand.
Macqueen, L. H.,	Watrous, Saskatchewan, Canada.
Magill, Jos. May,	Carpenterstown, Castleknock, Co. Dublin.
Meek, Ben. O.,	7 Bridge Street, Sydney, Australia.
Moir, Geo.,	G.V.S., Taiping, Perak, Federated Malay States.
Newbury, Thos. S.,	3 Palmerston St., Devonport.
Owen, G. E.,	c/o Department of Agriculture, Sydney, N.S.W., Australia.
Rix, C. E.,	7 Gubyon Avenue, Herne Hill, S.E.
Shacklock, J. Edward,	Castor, Alberta, Canada.
Smith, T. Assheton,	Kellerberrin, West Australia.
Welham, J. B.,	Sports Club, St. James Sq., W.

REVIEWS.

"THE CHEMISTRY OF CATTLE FEEDING AND DAIRYING." By J. ALAN MURRAY, B.Sc. (Edin.), Lecturer in Agricultural Chemistry at University College, Reading. London: Longmans, Green & Co. 6s. net.

The first part of the book is composed of chapters on the "Constituents of Plants and Animals," in which the author sets forth the classification and composition of the various mineral and organic constituents connected with feeding. The chapters on fats, amides, and proteins will be appreciated. The chemistry of proteins is a subject in which the ordinary agricultural chemistry student is not, as a rule, well informed, and an intelligent reading of this chapter will form a solid basis for a future superstructure. Mr. Murray devotes two chapters to Statics and Dynamics, subjects, which in dealing with the requirements of animals, have not received due justice among scientists in this country. It has been left to Germany to devise the respiration chamber experiments, and much of the world's most valuable work of this character has been done in that country. The author demonstrates the theories on which such experiments are based, and though this is usually the physicist's domain, we agree that it is advisable to include it in the book for those who have not had the opportunity of obtaining such knowledge.

When these chapters have been fully read the student should be ready to recognise the advantage of having the tables on the thermic and dynamic values of various foods, and their approximate cost. The articles on the constituents required for the production of meat and milk are fundamentally the same as those of previous writers, but there is wisdom in separating the maintenance from the fattening rations. As the author points out in calculating these rations, the two should be kept quite separate, and not considered in combination, as in former calculations. A table giving the average composition and price of various foods which are most used by farmers is added. Part III. deals with feeding stuffs, their analyses, methods of compounding, and valuation. It deals connectedly with the different merits, and emphasises the value accruing from method. Part IV. deals with Dairying, and it is treated very fully. The author gives a very interesting chapter on "Chemical Constituents of Milk." The paragraphs on preservative methods should be useful to students. The chapter closes with an account of an "Infants' Bottle Milk," a preparation which is now sold as "Humanised Milk." The book closes with a chapter on milk products and their analyses. To students preparing for examinations in agricultural chemistry there is hardly a more suitable work on scientific feeding. To farmers, except those who either by college or self-training are able to adapt scientific knowledge to their own needs, the book is not to be recommended.

SPECIAL PATHOLOGY AND THERAPEUTICS OF THE DISEASES OF DOMESTIC ANIMALS.—By DR. FRANZ HUTYRA, Professor of Infectious Diseases, and DR. JOSEF MAREK, Professor of Special Pathology and Therapy, both of the Royal Veterinary College at Budapest. Authorised American Edition, from the third Revised and Enlarged German Edition. Edited by John R. Mohler, V.M.D., and Adolph Eichhorn, D.V.S., both of the U.S. Bureau of Animal Industry, Washington. Vol. II. Translated by Maximilian Herzog, M.D., Professor of Pathology and Bacteriology in the Chicago Veterinary College, A. Leslie Sheather, M.R.C.V.S., B.Sc. London, England, and G. Mayall, M.R.C.V.S., Bolton, England. With 163 illustrations in the text and 5 plates. Ps. xvij. + 1018. Royal 8vo. Price £1 11s. 6d. net. (Baillière, Tindall & Cox, 8 Henrietta Street, Covent Garden, London).

This second volume of Hutyra and Marek's great work is almost as lengthy as the first one, and will probably be even more valuable to English clinicians. It is devoted to the diseases of the respiratory organs, the digestive organs (including the liver, pancreas, and peritoneum, the central and peripheral nervous system, the organs of locomotion, and the skin). It thus embraces a greater number of the conditions usually seen in everyday practice here than the first volume, which was chiefly concerned with infectious diseases, many of them unknown in this country.

All that we said of the general excellence of the first volume, in reviewing it a few weeks ago, applies equally to this one. The same depth and comprehensiveness of view, combined with breadth and equality of treatment, mark both volumes. Naturally the whole is not all of equal merit, and if we were to choose the portions likely to be most valuable to English readers, we should name a good many of the short sections upon equine and bovine gastro-intestinal troubles, and the bulk of the two hundred and odd pages upon nervous diseases. Regarding the former, it is needless to say that Marek's stomach tube—an instrument scarcely known in this country except by hearsay—is fully figured and described, together with the method of using it.

Further, the general diagnosis of abdominal troubles, especially perhaps rectal diagnosis, and manipulative treatment by the rectum, have been more closely

studied abroad than here, and this book contains the sum of Continental knowledge upon them. If its teachings are largely acted upon by our graduates, it may bring great changes into the treatment of the equine colics in this country. All that need be said of the pages upon nervous disease is that there are few important subjects regarding which practitioners generally stand in more need of accurate information, and the present account strikes us as on the whole the best and fullest we have seen.

The translation is good and clear, but the translators have introduced one or two words which we should be sorry to see established in our veterinary literature. For instance, such a word as "bloating," which is constantly used to signify emphysema and tympany alike, might surely be improved. On page 254 we notice a misprint—"sows" for "cows."

There are multitudinous points of interest in the book, and in many cases the views advanced are not in accord with English ones. For instance, in connection with obstruction of the œsophagus by a foreign body, we see no mention of the old English plan of small doses of oil *plus* patience, while some of the methods advised in its stead would strike many men as dangerous. Again, while Schmidt's milk fever treatment is recognised as valuable, it is suggested—not without reason—that its value may have been over-estimated. But the book covers so vast a field—including many little known as well as well-known conditions—that it cannot well be treated in detail, and it is best to summarise it by saying that it is a worthy successor to the first volume. Taking the two volumes as one work, we know of nothing in veterinary literature to compare with it for value. And, valuable as it is to the student, it should be even more so to the man in practice.

W. R. C.

PARLIAMENTARY.

In the House of Commons on Thursday, March 24th

Mr. CHARLES BATHURST, asked the President of the Board of Agriculture if there is any information available as to the possibility of preparing a diagnostic vaccine for John's disease from the causal bacillus, and whether he is aware that no public report has been issued upon this subject since September, 1912.

Mr. RUNCIMAN: The inquiry into John's disease, which is being conducted by the Royal Veterinary College, includes the question of diagnosis, and a large number of experiments and observations with regard to the relative reliability of different methods of diagnosis, including the use of "Johnin"—a test substance prepared from the causal bacillus—have been made. It is, however, considered advisable to obtain further evidence, and with this object "Johnin" is now being supplied gratis to veterinary surgeons for testing animals suspected of this disease. The College will publish a report on the subject as soon as the evidence collected appears to be sufficient to warrant definite conclusions.

March 19th.

FOOT-AND-MOUTH DISEASE.

In answer to Mr. C. BATHURST,

Mr. T. W. RUSSELL said:—The present position as regards foot-and-mouth disease in Ireland is as follows:—There were five fresh cases on Wednesday in scheduled districts in Cork—one in the city, one at Whitechurch, and three at Blarney. The disease does not appear to be active elsewhere. The real difficulty of the situation is in connection with consignments of calves that were sent from Cork to various places in the south. In five cases these animals were traced and disease found. In others the work of tracing is still going on in counties Waterford, Wexford, and Kilkenny,

but no outbreak has been reported. This difficult work has involved the scheduling of large areas of the country as a measure of precaution. But I trust the quest for these animals will soon be over and the country freed from the restrictions now imposed. In every case of disease it has been found to be connected with the cattle sale in Cork late in February.

Foot-and-Mouth Disease.

An outbreak of foot-and-mouth disease was confirmed on Thursday, March 19th, amongst cows on dairy premises in the Kirkdale district of Liverpool, and another outbreak was confirmed on Friday, the 20th, on similar premises in the Fairfield district of that city. Restrictions on the movement of animals have been in force in the city and surrounding district since the 23rd ultimo.

Another outbreak of foot-and-mouth disease was reported in Cork on Saturday, March 21st, within half a mile of the city.

The Board of Agriculture and Fisheries have been informed by the Department of Agriculture and Technical Instruction for Ireland of the issue by that Department on 25th inst. of an Order, the effect of which is to prevent the movement of animals, by sea or by land, from the southern part of Ireland into the northern part of Ireland. The boundary line between these two areas is approximately represented by the line joining the following towns: Drogheda, Navan, Oldcastle, Finnea, Mullingar, Moate, Athlone, Ballinasloe,

Athenry, and Oranmore. This Order will come into operation on 27th inst.

In consequence of this action, and in view of the general position as regards foot-and-mouth disease in Ireland, the Board have decided that they may now safely allow the importation of animals for slaughter from the northern area, and they have accordingly to-day made an Order authorising the landing of animals brought from the Irish ports of Dundalk, Belfast, Londonderry, and Sligo, to the authorised landing places at Birkenhead, Glasgow, and Manchester, where they will be required to be slaughtered within 96 hours after their landing. The Board's Order will take effect on Tuesday, 31st inst., and will thus permit of the shipment of animals from the northern area in Ireland on Monday night.

4 Whitehall Place, London, S.W.

March 26th.

Motor Taxes: Petrol Rebate.

In connection with Capt. A. C. Wilson's letter on this subject last week, we find that the matter has been mentioned in *The Veterinary Record* at the following pages:—

Vol. 21. May 8, 1909, p. 763: and pp. 772, 780, 793, 831, 845, 878-9.

Vol. 22. July 17, 1909, p. 68: and pp. 172, 248, 254.

Vol. 23. Sept. 24, 1910, p. 191: and pp. 208, 237, 364, 392, 442, 446-7, 463, 513, 540, 629, 671, 722.

Vol. 24. Aug. 5, 1911, pp. 94-5.

Vol. 25. Sept. 7, 1912, pp. 134-5.

Vol. 26. Oct. 18, 1913, p. 260: and pp. 294, 340, 384, 461, 524, 624.

(Established 1903).

8 Hartington Place, Ottawa, March 4.

Henry Gray, Esq.,

Dear Sir,—I beg to inform you that at the last annual meeting of the Central Canada Veterinary Association, held in the city of Ottawa on January 23, 1914, the members expressed their deep regret over the great loss the veterinary profession throughout the world has sustained in the death of Mr. William Hunting.

They felt that although they had not the honour of knowing him personally, they knew him through his various works, and admired him. In virtue thereof it was resolved that in view of the great benefit the profession has experienced through his labours they would like to assist you in your very commendable movement. Unfortunately, the funds of this Association are limited, but its members hope you will be good enough to accept this small subscription as a small token of their appreciation of one who worked unceasingly and unselfishly for the betterment of his profession, and whose accomplishments will make his name an honoured one for future years—Very sincerely yours,

(Signed) CHARLES EVANS, Sec.-Treas.

ARMY VETERINARY SERVICE.Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, March 20.

REGULAR FORCES. ARMY VETERINARY CORPS.

Lieut. W. St. J. F. McCartney is seconded for service with the Egyptian Army. Dated Feb. 1.

APRIL 4, 1914.

VOL. XXVI.

BOARD OF AGRICULTURE—THE CHIEF VETERINARY OFFICER'S REPORT FOR 1912.

In one direction this is one of the most valuable reports the Board has ever issued, in some others it is almost one of the baldest. Its value lies in its excellent account of the foot-and-mouth epidemic of 1912, which occupies all but about 4½ pages of the publication. "Foot-and-mouth" deserves all the space it receives, but the addition of a few more pages upon other diseases would have given the report much more value as a whole.

The matter concerning foot-and-mouth disease, which might have been very confusing to the reader, has been arranged very clearly. All the 1912 outbreaks in this island are divided into three groups—(1) Outbreaks which occurred in cattle from Ireland, or in cattle which had come in contact with the latter. (2) Outbreaks whose origin could not be definitely traced, but which occurred in districts into which cattle from Ireland have been imported in large numbers. (3) Outbreaks in which no connection whatever could be traced between importation of cattle and disease. The single outbreaks in each of these groups are carefully described in detail from the point of view of preventive medicine, special attention being paid to the important work of tracing the infection. Very often, in dealing with an individual outbreak, the reasons which guided the Board in deciding upon the precise rigour of the measures to be adopted are explained, and the report therefore abounds with illustrative examples of practical epizootiology. Some of the outbreaks, as the Sussex ones, are eminently instructive. The Chief Officer calls the final result of the year's work "a triumph for stamping out measures, when rigidly applied from the outset," and the facts justify his claim. But we wish that he had been able to give us some definite facts with regard to "those outbreaks which have been so numerous in recent years, and which we have every right to assume have been imported from the Continent in food stuffs or packing material, or in some other way." So long as our knowledge of the channels of infection from the Continent is so vague as this, we may expect fresh invasions of disease at any time, and it is well for us that our stamping-out measures are reliable.

Incidentally the report reveals that our English methods of veterinary inspection of markets are pitifully inadequate. In some concluding remarks upon the whole of the first group of outbreaks we find:—"It will be observed that most of these outbreaks were due to market infection, and it does not seem open to doubt that in some cases actually diseased animals were exposed for sale in markets. This leads us to ask if the distribution of disease

would not have been materially curtailed by provision of more adequate veterinary inspection of local markets? I think the answer must be in the affirmative, and I feel bound to point out that the veterinary inspector of one of the first infected markets informed me that his other duties left him only about forty minutes for the inspection of about 1500 animals in the market." This latter fact would be farcical if it were not also so serious—for the results are by no means confined to foot-and-mouth disease. It seems that some large markets have no veterinary inspection worthy of the name. It might be worth the while of inspectors to call the attention of local authorities to this paragraph in the report—few laymen can fail to appreciate its force.

The report deals with other scheduled diseases briefly, if at all. Sheep scab and parasitic mange are not mentioned. Anthrax receives a little attention, chiefly from the statistical side, and swine fever even less. In the latter connection reference is made to the losses from swine erysipelas, and to the fact that a good method of protective inoculation against it is available, but has not yet been taken up by pig-keepers. In the short laboratory report, we see a mere mention of researches being carried on by the Board upon several diseases—swine fever, epizootic abortion, louping ill, and scrapie. But upon the whole the last few pages of the report are not at all enlightening except as regards glanders.

The section on glanders is valuable from a careful comparison of the progress in 1912, with that of previous years. The Chief Officer points out that in 1912 the proportional decline of the disease received an unexpected check, and adds that the reason is engaging his attention. He finds one partial explanation for the check in the fact that the proportion of recurrent outbreaks in previously infected stables was higher in 1912 than ever before. This, to our mind at least, suggests that owners now keep and re-test old in-contacts more frequently than before; and if that is so the rise in recurrent outbreaks is a good sign. The Mines Act, too, led to the discovery of twelve outbreaks of glanders in 1912.

This section also contains some useful notes upon the proportional results of the mallein test, and the incidence of glanderous post-mortem lesions. If other sections had been as full as that upon glanders, the report would have been one of the most instructive we have ever had. But as it is, simply on account of its invaluable official history of the foot-and mouth epidemic, it is a noteworthy publication, and should be in the hands of every practitioner. The delay in its issue is, of course, accounted for by Sir Stewart Stockman's illness last year.

CLINICAL CASES.

FETAL DYSTOKIA.

Subject a big shorthorn dual purpose cow, presentation anterior, two fore legs, head doubled back, head could not be reached, so both fore legs were removed at the shoulders—and then we could not touch the head—could feel stifles of calf, but not head. Tracing the neck of fœtus, we cut a hole in the skin and inserted a blind hook. This drew the head forward so that I could get my hand in calf's mouth. Head straightened, calf delivered, and cow did well.

MATERNAL AND FETAL DYSTOKIA.

Subject: shorthorn heifer, first calf. Presentation anterior, head doubled back, could touch head but could not get it up. Cowman had fixed rope round lower jaw and pulled out the teeth. Could feel a band round calf's head just below the eyes, which I thought was afterbirth; removed it, and much to my surprise it was a circular band on the heifer's womb, about an inch wide, containing two cotyledons. The fore leg was removed and the calf delivered. Heifer killed on my advice.

HORN ON COW'S NECK.

While bleeding some pedigree milking shorthorns the other day I came across a small tubercle on the middle third of a cow's neck. The owner thought it was a wart. It was only attached to the skin. With his permission I cut it off and found it to be a perfect little horn, an inch and a half long, and the same shape as the cow's. Instead of a horn core it had a soft matrix, which looked like yellow firm cartilage.

VOMITION IN THE HORSE.

On March 17th last I was called to see a "chaser" which had run in our Point-to-Point (Old Berkshire), and found him vomiting all over the box. He was about 12 years old, and had previously won 13 consecutive Point-to-Points. The owner, who was riding him, found he was unwell at the start, and pulled him up after going two fields. On examining his neck I found on the lower left side of the jugular vein—not *œsophagus*—a thickening about an inch long, which felt like a stricture of the vein. The slightest pressure on this would make him arch his neck and "retch" tremendously. As we could not drench him, I gave him a hypodermic of morphia, and said would see him next morning. Next morning I had a telephone message saying the horse was alright, and was going back to Leicestershire by the 10.20 train. Had the thickening been in the *œsophagus* I could have understood the vomition, but being in the jugular vein it was a complete puzzle to me.

J. H. PARKER, M.R.C.V.S.

Faringdon, Berks.

ABSTRACTS FROM FOREIGN JOURNALS

HUMAN AND AVIAN DIPHTHERIA.

F. Arloing has published (*Bull. de Soc. Sc. Vét. de Lyon*) a long article upon this question. A long time before the bacteriological era, observation and clinical and epidemiological knowledge had permitted the supposition that the pseudo-membraneous diseases of poultry could sometimes be transmitted to man. At the present day the question of the relations between human and avian diphtheria is far from being definitely settled.

Avian diphtheria may appear in a per-acute, an acute, or a chronic form. The last named is the most common, and is characterised by pseudo-membraneous exudates, which may appear upon the buccal mucous membrane, and spread from there to the conjunctiva (ocular form) or to the pituitary membrane (nasal form). It may be caused by various microbes, which the author divides into three groups as follows:—(1) *Löffler's bacillus, the agent of human diphtheria.* (2) *Specific microbes, other than the true diphtheritic bacillus,* and (3) *Non-specific microbes.*

It is completely demonstrated that the true diphtheria of man may be transmitted to birds, experimentally or accidentally, by means of cultures or of diphtheritic material. On the other hand, the author reports facts which show that human diphtheria may be transmitted, not only to birds, but also to the pig, dog, and cat.

The bacteriological study of avian diphtheria has sometimes revealed the presence of the true Löffler's bacillus in the subjects, and sometimes that of a bacillus only differing from Löffler's by a lesser degree of virulence or by particular cultural or staining characters. Sometimes other specific microbes have been found, and sometimes, again, others without specificity. The very small microbe described by Bordet and Fally, and considered by them to be the true cause of avian diphtheria, should be remembered.

If we consider, on the one hand, the multiplicity of germs which have been described, and by means of which the affection has been reproduced, and, on the other hand, the variable results—positive in certain cases and negative in others—which have been obtained by means of the anti-diphtheritic serum, it appears logical to admit that there is not one avian diphtheria, but a number of avian diphtherias. According to the author, there exists in the bird (1) a true diphtheria, due to Löffler's bacillus, and (2) in addition to this true diphtheria, diphtheroid or pseudo-diphtheric affections which are related to true diphtheria by the similitude of their clinical symptoms, but nevertheless are due to microbes which have nothing in common with Löffler's bacillus.

The author draws a sharp distinction between the *diphtheroid exudate*, which is common to all cases of avian diphtheria, and the true *diphtheritic false membrane*, the formation of which seems to require the presence of Löffler's bacillus.

In man, the *true diphtheritic false membrane*, when fully developed, is generally opaque, greyish, verging upon white, or, if it is tinged by blood, darker in colour and sometimes brownish. It is lightly inserted in the mucous membrane, to which it adheres, and sometimes its removal causes slight hæmorrhages. *It does not disintegrate in water.*

This aspect is generally modified when the diphtheria is complicated by secondary microbial infections, the false membrane is then more diffuent and often has a putrid odour.

Histologically, the characteristic of the false membrane, which is engendered by the action of the toxins of Löffler's bacillus, consists entirely in the abundance of the fibrinous exudate, which constitutes the essential substratum of this production. The fibrin forms a network of large regular meshes, constituted by rectilinear fibrillæ. This fibrinous network is stained very deeply by eosin. Its superficial zone contains very numerous diphtheria bacilli in clusters and some super-added microbes (streptococci, staphylococci, etc.) Its middle zone contains cells that stain badly. Its deep zone contains diapedesised leucocytes, and epithelial cells which are still little altered, and have come from the subjacent mucous membranes. The latter appears congested and stripped of its covering epithelium.

In *false membranes due to Löffler's bacillus* in animals—whatever the species of animal that is concerned—one always finds identical reactions due to the specific action of the bacillus, and particularly the production of a *very important fibrinous network* upon the surface of the mucous membrane, which is deprived of its epithelium. On the other hand, the exudates found in birds in diphtheroid affections caused by other microbes than Löffler's are quite different in aspect. At first sight, to the naked eye, they resemble curdled milk, are friable, opaque, and greenish-yellow in colour. Generally they have a fætid odour, and *they disintegrate in water.* They are only slightly adherent to the mucous membranes, from which they are easily detached. Sometimes these productions are hard, dry, and scaly.

Microscopically these *pseudo-false membranes*, as the author calls them, are formed by elements affected by coagulation—necrosis invaded by innumerable leucocytes. At no part do they show the staining reaction of fibrin.

The appearance of the "pseudo-false" membrane in avian diphtheria may be explained, not by a precipitation of fibrin, but by an elevation of the epithelium, which is lifted and dislodged by a veritable inundation of leucocytes, and at the same time becomes imbibed and swollen.

It results from these observations that, in avian diphtheria, the presence or absence of the fibrinous substratum in the false membrane should enable a decision to be made as to whether the disease is due to Löffler's bacillus or to other microbes.

In the latter part of his communication, the author produces many clinical facts which demonstrate the transmission of avian diphtheria to man, and, reciprocally, the transmission of human diphtheria to certain animal species.

The principal conclusions resulting from this work may be tabulated as follows ;—

1. It must be admitted that avian diphtheria is polymicrobial in nature.
2. Pathological anatomy enables the true diphtheria, due to Löffler's bacillus, to be differentiated from diphtheroid affections due to other germs.
3. Reciprocal contagion between animals and man is possible, whatever the microbe causing the disease may be.—(*Annales de Méd. Vét.*)

THE OCCURRENCE OF AVIAN TUBERCULOSIS IN MAN.

E. Löwenstein says (*Wiener Klinische Woch.*) that the eggs of tuberculous fowls contain numerous tubercle bacilli; and that when the egg is cooked, as is usual, to the consistency of a plum, these bacilli are not killed, and may provide a source of infection for mankind. He has repeatedly seen cases of avian tuberculosis in human beings, in which he bacteriologically identified the avian tubercle bacillus both by cultural experiments and animal inoculation. When acid-fast bacilli are found, not only should guinea-pigs be experimentally inoculated, but also rabbits and fowls.—(*Berl. Tier. Woch.*)

SUBCUTANEOUS TUBERCULOSIS IN A COW.

Ch. Pérard, a sanitary veterinary surgeon of the Seine, reports the following peculiar lesions which he observed in the abattoir. The subject was a cow of Normandy breed, about ten years old. She had come from a dairyman's establishment, and was affected with pulmonary tuberculosis. The lesions in question were found in the middle part of the left side of the neck.

These lesions consisted of small irregularly bunched tumours, ranging from the size of a millet seed to that of a lentil, and either united in little clusters or not united. They were situated in the subcutaneous connective tissue, in the thickness of which they formed a plastron about six inches in diameter and from 1-5th inch to 2-5th inch thick.

Some of the tumours were adherent to the internal face of the derma, and others to the external face of the superficial muscles. A large number of them had therefore been divided by the butcher's knife. Upon section, they appeared clear yellow in colour and fibrous in consistence. A certain number showed the commencement of calcification. The neighbouring lymphatic glands showed no signs of tuberculosis.

The author, in conjunction with Ramon, has already studied and described (*Bull. Soc. Centrale de Méd. Vét.*) subcutaneous tuberculous lesions of cattle, some of which resembled the "tuberculides" of Darier and Rousy. The lesions under notice were absolutely different to the previously described ones. Those first described by the author and Ramon consisted of round or oval nodules, surrounded by a fibrous envelope, of the average size of a nut, of elastic consistence, and composed of a homogeneous substance of greyish colour. The lesions under notice, on the other hand, were small hard bunched tumours, fibrous or partially calcified, and of a beautiful yellow colour.

The fact that she showed unequivocal signs of tuberculosis elsewhere rendered these cutaneous lesions especially suspicious.

Direct microscopical examination of scrapings from these lesions, stained by Ziehl's method, yielded no positive result. Animal inoculation, on the other hand, did give positive results. Two guinea-pigs were inoculated hypodermically with substance obtained by crushing these lesions, and both died—in fifty-three and fifty-eight days respectively. The post-mortem examination showed that they had succumbed to a tuberculous infection.

Finally, the author mentions that, according to the information given by the cow's owner, she had some months previously received a hypodermic injection of tuberculin on the left side of the neck. The author suggests that this may possibly have been concerned in the production of the post-mortem lesions found in the same region.—*L'Hygiène de la Viande et du Lait*.

(English tuberculins are all at least supposed to be sterile—are all French ones? The final paragraph suggests a doubt.—*Transl.*)

THE ACTION OF COD LIVER OIL AGAINST FLIES AND MOSQUITOES.

Lang, a Government veterinary surgeon of Noumea, has been studying the action of cod liver oil upon the "flat-flies" (*Hippoboscidae*) which assail animals. He finds that this oil possesses a specific toxic action upon all flies, and upon mosquitoes and ticks.

By covering those parts of the horse's body which the "flat-flies" most affect with cod liver oil, it is possible to instantly destroy all the flies which the oil even slightly touches. It is also possible, with the oiled hand, to free the horse within a few minutes of all the flies of which he is the host, without fear of a subsequent caustic action upon the skin.

The same action is manifested against flies, mosquitoes, and even against ticks, which are so difficult to extract from the skin of the dog.

Moreover, cod liver oil has a prophylactic effect. When placed upon wounds it obstructs the action of flies, and thus favours cicatrization.

Its greatest drawback is its strong smell.

Finally, if sprinkled upon the surface of water it destroys larvæ more effectively than petrol, and the author advises its use in preference to the latter agent as a prophylactic against mosquitoes.—*La Semaine Vét.*

A COMBINATION OF NARCOTIC AND ANÆSTHETISING AGENTS IN VETERINARY SURGERY.

Roger describes (*Revue de Méd. Vét. Militaire*) the following method, which he uses for surgical operations upon the horse, and which combines the action of two narcotics, sulphonal and chloral hydrate, with that of opium, a narcotic and anæsthetic. His procedure is as follows:—

1. From the evening before the operation onwards, the horse receives nothing more to eat.

2. Two hours before the operation, he is given 500 grammes (about 7/8 pint) of water, in which 20 grammes (about 3v.) of sulphonal is dissolved.

3. Half-an-hour after taking the sulphonal, he receives a clyster of chloral hydrate (the amount of this is not stated.—*Transl.*)

4. A quarter of an hour before being thrown for operation, he receives a hypodermic injection of half a gramme (nearly 7½ grains) of morphia.

This method has given the author excellent results, and has enabled him to operate just as conveniently as with the aid of general narcosis.—(*Berliner Tier. Woch.*)

[When a clyster of chloral hydrate *alone* is used for this purpose, as it often is upon the Continent, about 80 grammes is the common dose.

In the method described above, no doubt a much smaller dose is used. The most remarkable feature in Roger's procedure is the employment of sulphonal, which hitherto seems to have been very little used in equine practice.—*Trans.*]

THERAPEUTICS OF PARENCHYMATOUS MASTITIS.*

By LOUIS A. KLEIN, University of Pennsylvania.

The pathological alterations of parenchymatous mastitis show a striking similarity to those of pneumonia. There is an exudation of blood serum and an immigration of leucocytes and wandering connective tissue cells into the acini and ducts of the gland, which is accompanied by an exfoliation of the epithelial cells lining the acini and ducts. There is also an inflammatory exudate into the interstitial and subcutaneous connective tissue, which is sometimes very pronounced. If these exudates can be removed and the epithelium is capable of regeneration, resolution occurs. If the exudates are not removed and the circulation is not restored to normal within a certain period, the inflammatory process in the interstitial tissue assumes a productive character. An increase of the interstitial connective tissue occurs and the udder becomes indurated. Subsequently, the newly-formed connective tissue contracts and produces atrophy. The epithelial cells disappear in such cases, either as a result of the pressure from the contracting connective tissue or because of extensive destruction at the beginning of the disease. If the milk ducts or canals are obstructed by clumps of casein or fibrin, the pathological secretion will be dammed up and abscesses will form. If the circulation is cut off from a section of the inflamed area by thrombosis or by pressure from the inflammatory exudate or collections of pus, necrosis or gangrene will occur. The necrosed area is subsequently separated from the healthy tissue by suppuration and may then become encapsulated, or, as occurs more frequently, the line of demarcation may extend to the surface, when the sequestrum may be eliminated spontaneously or removed by operation.

Resolution and the avoidance of complications, it will be seen, depend upon the prompt removal of the exudates. The exudate in the acini, ducts and cistern can be drawn off by milking, but that in the interstitial tissues must be resorbed.

Resorption is a complex physiological process which cannot be generated by artificial means, but the natural

* Presented at the fiftieth anniversary meeting of the American Veterinary Medical Association, at New York.

processes concerned can be stimulated or increased in capacity by certain therapeutic methods. The principal factors concerned in resorption are the interchange of fluids between the blood and tissues, the leucocytes, and the quantity of blood flowing through the part. By utilising these natural forces resorption can be promoted.

Purgatives and diuretics increase the interchange of fluids between the blood and tissues. By causing a reduction in the fluid of the blood they cause fluid to be absorbed from the tissues. This is known as the derivative or revulsive method. Sialagogues and diaphoretics also produce a derivative effect. The most striking illustration of the effectiveness of this method is the result obtained from the use subcutaneously of arecoline, a purgative and sialagogue, in the treatment of laminitis in horses. In parenchymatous mastitis, it is customary to use magnesium sulphate as a purgative, but eserine and pilocarpine combined act more promptly and perhaps more thoroughly and effectively, since they are sialagogues as well as purgatives, although their cost may prohibit their use in some cases. Arecoline is not recommended for cattle. On account of their weakening effects, purgatives cannot be repeated, but the derivative action can be continued by the use of diuretics. Potassium nitrate is a very popular diuretic in the treatment of parenchymatous mastitis, but one of the less irritant saline diuretics would be more desirable. Phytolacca, which has been used empirically in the treatment of mastitis for a long time, has a diuretic action and no doubt exerts its effects in this way. Diaphoretics are of no practical value as derivatives in cattle practice.

Leucocytes assist in resorption by phagocytosis and causing the disintegration and solution of solid exudates by means of a ferment. Leucocytosis may be increased by the local application of stimulants, such as tincture of iodine, spirits of camphor, oil of turpentine, etc., and by other measures which increase the flow of blood to the part, as hot water bathing, vapour baths, Priessnitz dressing, poultices, plasters, frequent milking and massage. According to Hess, massage should only be used after the inflammation has begun to subside and pain has disappeared. If it is applied at the height of the inflammatory process the disease will be extended to the adjoining quarter on the same side or on the opposite side, and the secondary infection is usually more severe and more difficult to heal than the original process. Massage is also contraindicated when suppuration or necrosis is present. Phagocytic function of the leucocytes can be stimulated by the injection of bacterins, but this action is a specific one, and the bacterin is only effective for the particular species of organisms used in its preparation. Since parenchymatous mastitis is a polybacterial disease the preparation or selection of a suitable bacteria for each case would involve considerable detail work. Schmidt, of Kolding, Denmark, the discoverer of the successful modern treatment of milk fever, recommends as a substitute for bacterins, the infusion into the udder of equal parts of absolute alcohol and glycerine. This mixture, he says, will kill and dissolve numbers of the bacteria concerned in the disease and when these dissolved substances are absorbed, specific opsonins will be produced which will stimulate the phagocytic action of the leucocytes against the bacteria remaining in the udder. But the mixture has a destructive action upon the epithelium of the udder and for this reason can only be used in those severe cases where the life of the animal is threatened or where there is no prospect of the return of the milk secretion. In other cases, the mixture is diluted with an equal amount of physiological salt solution. Usually about 250 c.c. is infused into the infected quarter and the quarter is not milked out for three days. The disintegrating and solvent action of the leucocytes on solid exudates cannot be directly affected by drugs, but a similar action

can be obtained with potassium iodide, which destroys pathological cells and causes them to degenerate, and by sodium chloride, sodium bicarbonate, sodium sulphate, and ammonium chloride, which dissolve and liquefy solid inflammatory products.

An increased flow of blood through the part may be brought about by heart stimulants, local stimulant applications, hot water bathing, vapour baths, Priessnitz dressing, plasters, poultices, massage, and frequent milking. Caffeine will serve the purpose of both a heart stimulant and diuretic, and may be given in the form of the alkaloid or strong coffee. Frequent milking, every one or two hours, is a very important method of treatment. The manipulation of the test dilates reflexly the blood vessels of the udder and causes a greatly increased amount of blood to flow through the udder. It also removes the exudate and prevents its decomposition and the formation of irritant bacterial products in the acini and ducts of the udder. A suspensory bandage promotes the circulation in the udder and also reduces pain by relieving tension upon the tissues.

When it was demonstrated in the last quarter of the nineteenth century that bacteria were the direct cause of mastitis, Franck advocated that the disease be treated by destroying the bacteria concerned by the injection of antiseptics into the udder. This method of treatment was adopted by many veterinarians, but the results were disappointing. It was found that the antiseptic solutions irritate the udder tissue and frequently increase the inflammation even when diluted to a point where their effectiveness seems doubtful. Subsequently it was observed that all of the beneficial effects resulting from the injection of antiseptic solutions could be obtained by frequent milking without the irritation produced by antiseptics.

Some antiseptics when administered by the mouth are eliminated through the udder. The writer administered hexamethylenamina, better known under the name of urotropin, to a cow in one to two dram doses and demonstrated formaldehyde in the milk in 24 hours. Boric acid given in two to six dram doses at the same time to the animal appeared in the milk in 12 hours. No irritant effects were produced. Iodine is eliminated in the milk when potassium iodide is given and salicylic acid is also excreted through the udder. When doses of 45 grains to 1½ drams of potassium iodide were given daily, Labourdette found that the milk contained up to 3½ grains of potassium iodide to the quart. The amount of the other substances eliminated in the milk has not been determined.

The germicidal power of milk, which is feeble under normal conditions, is increased in mastitis. Its effect on the bacteria of mastitis has not been accurately tested, but the writer has observed a few cases of streptococcal mastitis in which it appeared to have destroyed the organisms of the disease. Whatever advantage can be obtained from this property can be exerted to the fullest extent by frequent milking of the affected quarter.

While bacteria are usually the direct cause of mastitis there are certain accessory or predisposing causes which should receive consideration in treating the disease. These are damp, cold floors, sudden exposure to cold air, excessive cold, drafts, incomplete milking and stasis of milk. Deep milkers are more susceptible to the disease than others.

Usually the fever is reduced by the action of the purgative and the diuretics. Very high temperature indicates septic infection and camphor, alcohol and quinine are then indicated. Necrosis, abscess formation, indigestion, paresis of the rumen, muscular weakness, posterior paralysis and other complications are treated according to the usual methods.—*American Vet. Review.*

WESTERN COUNTIES
VETERINARY MEDICAL ASSOCIATION.
[NATIONAL V.M.A. SOUTHERN BRANCH.]

The 31st annual meeting was held at the Royal Clarence Hotel, Exeter, on Thursday, March 26th, when the President, Mr. C. E. Perry, of Bristol, occupied the chair. Others present included Capt. A. S. Head, Helston; Messrs. Wm. Ascott, Bideford; W. H. Bloye and P. G. Bond, Plymouth; A. J. Down, Sampford Peverell; J. Dunstan, Liskeard; G. H. Gibbings, Tavistock; G. Lansley, Axminster; P. Penhale, Barnstaple; R. E. L. Penhale, Torrington; Wm. Penhale, Holsworthy; Wm. Roach, Exeter; W. P. Stableforth, Colyton; E. J. Thorburn, Crewkerne; and H. E. Whitmore, Langport.

The minutes of the last meeting were read and confirmed.

Apologies regretting inability to attend were read from Prof. Hobday, Messrs. E. Dunstan, F. T. Harvey, W. L. Richardson, A. G. Saunders, and W. Wintle.

Correspondence. Mr. G. Parker Short wrote from a Nursing Home in London, thanking the members for their vote of condolence passed at the last meeting.

THE LATE MR. WM. HUNTING.

It was unanimously resolved to support the proposed petition to the Treasury, and the President was empowered to sign a copy of the same on behalf of the Association.

On the motion of Mr. R. E. L. Penhale, seconded by Mr. Wm. Penhale, it was resolved "That the sum of three guineas be subscribed to the Fund being raised in recognition of his life and work."

A letter from Mr. J. C. Coleman, of Swindon, asking to be supported in his candidature for election to the Council in May, was read.

The notice of the Congress of the Royal Sanitary Institute, to be held at Blackpool in July next, was allowed to lie on the table, the distance being considered too great to appoint delegates.

The Hon. TREASURER (Mr. P. G. Bond) presented the annual report and balance-sheet, and on the proposition of the President, seconded by Mr. Ascott, the same was approved and adopted.

ELECTION OF OFFICERS.

Mr. W. P. STABLEFORTH was unanimously elected President for the ensuing year, and Capt. Head, Messrs. C. E. Perry, Wm. Penhale, and G. Lansley, vice-presidents.

Messrs. P. G. BOND and WM. ASCOTT were re-elected Hon. Treasurer and Hon. Secretary respectively, and heartily thanked for their past services to the Association.

The arrangements for the next meeting was left in the hands of the President, Hon. Treasurer and Secretary.

EPIZOOTIC ABORTION.

By Capt. A. S. HEAD, F.R.C.V.S., Helston.

Definition. A specific, contagious, catarrhal inflammation of the pregnant womb, with an oedematous condition of the foetal membranes. The chief symptom being the expulsion of the foetus prior to the full time of gestation.

It is a disease which has, possibly, from early times down to the present time, caused as much loss financially to dairy farmers and breeders as any other disease, but owing to the fact that it does not cause loss of life to the affected animal, it has not been studied until latter years, or received the attention it deserves;

and even now we are without legislation on the subject. To many a dairy farmer it means financial ruin to have his herd infected with the disease.

The disease usually at its outset affects all, or nearly all, of his cows. His supply of milk fails through the cows slipping, and not calving at the time that he has arranged and requires their milk, so he has either to buy new cows in full milk to supply his customers, and feed the cows that have slipped, or try to breed from them again. I have known dairy farmers that have not had a live calf for a whole year. When one thinks of this one can only wonder why, in our land of so many laws, some steps have not been taken to check the ravages of the disease.

The disease is caused by Bang's bacillus, which is rather like the tubercle bacillus, but smaller. The larger bacilli have a beaded appearance when stained, with rounded ends, are non-motile, do not sporulate, and have a great tendency to clump or group together which, under the microscope, look like micrococci.

Staining Reactions. With all watery solutions, but not by Gram. The best and easiest methods are, I think, $\frac{1}{2}$ carbol-fuchsin and $\frac{1}{2}$ water, or a weak solution of methylene blue.

The bacillus is found chiefly in the exudate between the uterus and chorion. At the time of abortion a smear taken from this exudate shows large quantities of bacilli. The bacilli can also be found in the substance of the cotyledons and the foetal stomach.

Cultivation. The bacilli can be grown on gelatine, agar serum, at about body heat.

Susceptibility. Bang's bacillus has not been found in any animal but the cow, and has never been found in the bodies of the male or the virgin female, although it has been given experimentally to the mare and goat.

An attack of the disease, provided that the cow is allowed to thoroughly recover from the disease before being again served, gives a certain amount of immunity. Two attacks render a very large proportion of the herd immune; this acquired immunity lasts probably for several years, but I have known one cow to have the disease four times, and many others three times. An aborted calf that lives probably also has a lifelong immunity.

Natural Infection. I believe that I am right in stating that it is now widely believed that the most common mode of infection is through the alimentary canal. It is well known that animals can easily be infected experimentally in this way.

The next most common way will probably be found to be due to infection by biting flies. I put infection by the bull last, but as quite a possible way. In everyday life a farmer keeps a bull, and he usually puts an outbreak of abortion down to some infected cow being brought to his bull to be served. I think that this is quite possible, provided that his bull afterwards serves a clean cow of his within a few days.

I think that the most probable explanation is, putting aside the question of a dog bringing an aborted foetus on to his farm, or his neighbours having infected boots, that an infected cow comes to his farm, discharging and dropping bacilli all over his yard and bull box, the bull gets it on his feet and chest, the farmer himself and his men step in it, and then walk over the fields and into the cowsheds, and his cows pick it up from the grass or bedding, or flies alight on the discharge and carry it to other cows and infect them by biting or through sores. That, and the want of proper care in the disposal of the placenta and foetus of infected cows, are the chief causes in the spread of the disease. Another great factor in the spread of the disease I will mention later.

Diagnosis. It is not possible at present to diagnose the disease with any certainty before the principal symptom, i.e. abortion, has occurred. Experiments have been made with "Abortin," which, like tuberculin,

is said to give a temperature reaction, but even if we could diagnose it we cannot cure it, and so, with the exception of isolating all cows that react, from a practical point of view it would be useless to us.

When abortion occurs, diagnosis within 24 hours is simple. Besides the fact that the exudate contains large numbers of bacilli, the placenta itself is a great guide; it has a distinct yellow, gelatinous, watery appearance, quite unlike a normal afterbirth. In nearly all cases it is retained, and there is a very peculiar smell attached to an abortion placenta that may be best described as "musty."

Curative Treatment. The market, under various headings, is full of so-called cures for the disease, the majority having carbolic acid as their base, disguised in many ways; some give the acid in the food, others as a drench; some again vaporise the acid with a certain percentage of liquorice to disguise the smell, and others spray it into the vagina. They all claim, and I must admit with some right, to cure the disease. Their success is due to three factors:—

(1) With all preparations, either inhalations, or per os, etc., there are directions as to isolation, disinfection, and the disposal of manure, foetus, afterbirth, etc., this alone does a lot.

(2) The farmer begins to wake himself up to the nature of the disease, and takes steps to stamp it out.

(3) By the time that the farmer is awake and finds that he has abortion on the farm, half the battle is over, the herd is beginning to immunise itself.

He has probably got over the first all-round slip, and many of the cows during the second year will carry their calves full time; and those that slip will carry their calves longer than they did the previous year. At the third year his whole herd is practically immune, and he then writes a testimonial stating that: "One year after using your medicine it completely stamped out the disease on my farm": so are reputations made.

I myself know of no cure once the disease has attacked a cow, and until the act of abortion has taken place, or full-time calving has taken place. I say this as it is quite possible, and sometimes happens, that a cow has contagious abortion and yet carries the calf full time, and when she calves, bacilli can be found in her in great numbers; but I believe that one can prevent an outbreak, cut an outbreak short, and protect stock that have not already got the disease from getting it even when on a badly infected farm.

Prevention and eradication. I believe that the first necessity is a law making the disease notifiable, and preventing the exposure for sale (except for food purposes) of any cow or heifer on the farm until that farm is certified to be clean.

It is now a common practice among a certain class of farmers and dealers to put another calf on to a heifer or cow that has aborted, and as soon as they take to the new calf, send them to the market as a newly calved cow or heifer. One can imagine nothing more criminal than this; for the cow is simply dropping bacilli everywhere, and the new owner's farm is soon thoroughly contaminated. A severe penalty is required to check this practice.

The next question is the advice that we should give an owner of a contaminated farm. I think the following are the chief points:—

(1) Don't buy any fresh cows or heifers if it can be avoided, as they are certain to catch the disease, and so keep the disease running; keep and re-breed from all your cows that have aborted if possible, they are less likely to abort a second time than a new cow, and are nearly certain not to abort a third time. Naturally, one would keep all cows that do not abort, as they have a natural immunity.

(2) After calving, if the after-births don't come away naturally, have them removed—the cows clean up sooner and the time that they are spreading infection is therefore shorter.

Isolate aborted cow until clean.

(3) Keep your own bull.

(4) Watch your herd carefully, see every cow yourself, and look for signs of abortion: then isolate at once.

(5) Burn or bury the foetus and afterbirth, and mix the dung and bedding from an aborted cow with lime and use on ploughed land, or, better still, in the kitchen garden.

(6) Use a disinfectant spray, and disinfect your cows behind daily.

(7) Keep every cow that calves two months before going to the bull again. This, I believe, gives the cow time to completely recover from the disease before the uterus is again impregnated.

(8) A cow that has aborted should be kept two months after cleansing has ceased.

I believe in the importance of keeping the cows empty for some time for two reasons: (1) It gives the cows time to get over the disease; (2) After abortion you get a percentage of cows that will not hold (keep returning to the bull).

There only two ways that I have found give any satisfaction in the treatment of this trouble: (1) Keep the cow away from the bull for a lengthy period; (2) Well wash out the vagina with an antiseptic solution, and then let the bull serve and inseminate her.

Protective inoculation. We know that attacks of the disease render the animal immune, therefore by giving the animal the disease, or, in other words, injecting a proportion of the live bacilli into the subject when she is empty (at a certain length of time before being served by the bull) so that she may recover from the disease before becoming pregnant, should cause immunity. For the last three years I have, under the instructions of Sir Stewart Stockman, been experimentally inoculating cows in this way with material supplied by him.

The figures are not mine to publish, and as experiments have been and are being carried out in other parts of the country, I understand Sir Stewart Stockman naturally wishes to publish the results as a whole, and I believe that this will be done at a very early date. I do not think I am indiscreet in stating that I have inoculated nearly 1,000 cows, and for my part the experiment has proved to me that this line of treatment will be universally adopted in a very short time.

This and legislation, and a better education of the farmers on the subject will, I am certain, in a few years place contagious abortion in the same category as rabies and pleuro-pneumonia.

Vitamine.

A definite substance has at any rate been extracted from rice-polishings, yeast, bran, and milk which forms a small though apparently a very essential part of food-stuffs, inasmuch as their value as nutrients is impaired without its presence. The so-called "deficiency diseases" appear to arise from the use of foods from which vitamine has been removed. The substance appears to be a pyrimidine base analogous to uracil and thiamine and is probably a constituent of nucleic acid. It is definite enough to be crystallisable, the crystals giving a constant melting point. It is to be hoped that this substance will be the subject of further active researches, for the importance attached to the chemistry of foods seems to diminish in contrast with the vital influence of this remarkable base in dietetics.—*The Lancet*.

Department of Agriculture, Union of South Africa.

VETERINARY DIVISION—DISTRIBUTION OF OFFICERS.

Principal Veterinary Surgeon: C. E. Gray. Assistant Principal Veterinary Surgeon: J. D. Borthwick.

Cape Province.—Senior Veterinary Surgeon: R. W. Dixon, Capetown. G.V.S.: A. Goodall, W. Jowett, and E. Fern, Capetown; R. P. Jones, East London; J. H. L. Lyons, Graaff-Reinet; W. P. Hamlyn, Komgha; A. Matthew, Elliot; W. A. Simson, Cradock; W. Jones, Uitenhage; J. Nichol, Kingwilliamstown; W. G. Pakeman, Queenstown; J. P. L. Goemans, Vryburg.

Transvaal.—Senior Veterinary Surgeon: J. M. Christy, Pretoria. G.V.S.: R. S. Garraway, Pretoria; W. G. Evans, Volksrust; P. Conacher, Johannesburg; J. I. Edgar, Pietersburg; G. May, Rustenburg; H. M. Webb, Carolina; G. C. Webster, Barberton; J. Chalmers, Ermelo; J. M. Tate, T. H. Dale, Potchefstroom; J. G. Bush, Krugersdorp; G. Lee, Middelburg; F. Dunning, Lydenburg; G. McCall, Nylstroom.

Natal.—Senior Veterinary Surgeon: W. M. Power, Pietermaritzburg. G.V.S.: S. H. Ewing, Eshowe; A. F. Harber, Durban; S. I. Johnston, Mooi River; F. J. Hill, Ladysmith; A. Goulé, Maritzburg; J. L. Webb, Bulwer; C. Tyler, Port Shepstone; and F. Hutchinson, Dundee.

Orange Free State.—Acting Senior Veterinary Surgeon: G. W. Freer, Bloemfontein. G.V.S.: J. F. Joyce, Ficksburg; J. R. R. Hamilton, Bloemfontein; F. M. Skues, Bethlehem; C. H. Wadlow, Smithfield; and E. T. Clemow, Frankfort.

Transkeian Territories.—Senior Veterinary Surgeon: J. Spreull, Umtata. G.V.S.: A. M. Howie, A. C. Kirkpatrick, R. Paine, W. A. Dykins, J. J. G. Keppel, and J. A. Worsley, Umtata.

DIVISION OF VETERINARY RESEARCH.

The Division is in close touch with, and is complementary to, the Veterinary Division. Director of Veterinary Research: Sir Arnold Theiler, K.C.M.G. Assistant Director of Veterinary Research: W. Robertson, Grahamstown. Superintendent: E. P. H. Parkes. Professional Assistants: D. T. Mitchell, W. H. Andrews, D. Kehoe, F. Veglia, G. A. H. Bedford, J. Walker, E. M. Robinson, H. H. Green, and P. R. Viljoen, Allerton.

Lamziekte Research Stations: Christiana (Officer in charge: W. H. Andrews), and Armoed's Vlakte (Officer in charge: R. R. Sharpe).

A Dangerous Dog.

A person is entitled to keep a dangerous animal upon his premises, but if he does so he is under the absolute duty of seeing that such animal does not escape. If it does escape, he is liable for any damage caused by it. In a recent case that rule has received some modification. A dog, the property of the defendant's daughter, had previously bitten another dog, and both the defendant and his daughter knew this. The dog was in fact the property of the girl herself, who was seventeen years of age; she had paid for the licence, which was in her name. She lived with her father, and the dog was also in that house. It happened that the dog worried and killed a Pomeranian dog, and its owner sued for damages, directing the action not against the girl but against her father. In the circumstances, and taking into consideration the age of defendant's daughter, the Court held that she had the custody and control of the dog, and that her father, who was not the owner of the dog, owed no duty to the community in respect of it.

In a case lately heard in the Falkirk Sheriff Court, the evidence clearly showed that the pursuer had been bitten by defender's dog, and that the defender knew that the dog was of a biting disposition; but the further question emerged whether, in the circumstances, the defender was liable, for the injury had been received by the pursuer when he was walking along a road through defender's farm steading, where there was a custom of passage not amounting to a right-of-way, but tolerated by the defender and his predecessors in the farm for many years. The argument for the defending farmer was that pursuer was a trespasser, and was at the steading on his own risk; but the Judge thought that as defender had acquiesced in persons using the road, there was laid on him the duty of controlling vicious animals so as to prevent them injuring passers-by, and accordingly he found the defender liable in damages.—*The Scotsman.*

Mange Prosecution at Hartlepool—Dismissed.

At the West Hartlepool Police Court on Wednesday, 25th ult., before Dr. Davis (in the chair) and Colonel Lauder, Joseph Thomason was charged with an offence under the Diseases of Animals Act.

Mr. Higson Simpson (the Town Clerk) prosecuted. He said the Order known as the Parasitic Mange Order of 1911 provided that a person having in his possession any animal suspected of parasitic mange should keep the animal separate and comply with certain other conditions.

Inspector Kevan said that on Saturday the 31st January his attention was called to a horse belonging to Mr. Pattison and which he found to be suffering from parasitic mange. He stopped the horse from being used. Accompanied by the Corporation veterinary inspector he went to the premises of the defendant and there found a mare suffering from parasitic mange.

Benjamin Hoadley, M.E.C.V.S., veterinary inspector employed by the Corporation, said that on the 1st Feb. he received notice of the defendant, went to the premises and there saw a bay mare. In his opinion it was a very bad case of parasitic mange. From the condition of the animal the disease had been in existence for at least three months. Mr. Emmerson Thomason said they had been treating it with paraffin oil and trying to cure it. Paraffin oil was not a proper remedy. He put some hair from the animal under a microscope, and found this particular parasite.

Cross-examined, the witness said there were lots of skin diseases and three specific forms of mange. A mere novice would be able to detect the presence of the disease once he had seen it.

James G. Dean, M.E.C.V.S., of Bishop Auckland, spoke to visiting the premises on the 4th Feb. He found a bay mare suffering from parasitic mange. It was general all over the body. It was a very bad case, so bad that any person who had seen a case of parasitic mange before could not mistake it.

Mr. Berry, for the defence, said that his client had had a vast experience of horses. They were asked to believe by the prosecution that he had allowed a mare suffering from this contagious disease to be amongst other horses. That was an unreasonable proposition. They had no proof that there was a reasonable suspicion of the mare suffering from mange. His client believed that the mare was suffering from an ordinary skin disease due to overfeeding, and he allowed his man to take the usual precautions. When his client thought there was a suspicion of the mare suffering from mange he immediately gave notice.

Joseph Thomason, manager for Messrs. J. J. Thomason and Co., hay and corn merchants, said on Dec. 12th he purchased a horse from a Mr. Beach, and on Dec.

19th he exchanged it for another one with Mr. Pattison. The horse he got from Pattison was a grey gelding, and there was not anything wrong with either horse. At that time he had a bay mare in his possession, and that animal was the object of the charge. That animal he had owned for three years, and in December last he noticed that there was a little rash or eczema—common among horses—upon it. This, he thought, was due to heat in the blood, for in the back end or spring of every year since he had the animal it had been similarly afflicted. There were six other horses in the stable along with that horse, and he most certainly would not have allowed the mare to be among the other horses had he suspected parasitic mange. On Jan. 31st witness heard that Mr. Pattison's horse had been stopped, and in consequence of that he saw Mr. Walker, the veterinary surgeon, and asked him to look at his mare. Mr. Walker could not find anything relating to parasitic mange.

Emmerson Thomason said he did not think the horse in question had suffered from parasitic mange. The harness used by this horse had also been placed upon other animals, and those horses had not shown the least symptoms of the mange. The horse had suffered from a slight scurf, which had been treated with paraffin.

John M. Walker, F.R.C.V.S., veterinary inspector for the Petty Sessional Division of West Hartlepool, and for Hartlepool, stated that on January 31st defendant told him that Pattison's horse (which had come from his stable six weeks before) had been stopped on account of parasitic mange, and he asked witness to examine the mare concerned in this case. He did so the following morning, and found new hair growing along the back and flanks. He considered that the condition of the horse's skin was then due to the paraffin. Witness advised Mr. Thomason to get a second opinion, and reported the case as a suspected one, as a precautionary measure. He, however, was of the opinion that the horse had not had parasitic mange.

The Chairman: In your opinion, under the conditions, would it be very difficult for a layman to detect whether it was a case of parasitic mange?

Witness: Most certainly.

The Bench found that defendant had not had reasonable suspicion that the animal was suffering from parasitic mange between January 1st and 13th, and they therefore dismissed the case.—*Northern Daily Mail*.

Dispute about a Gelding.

At Castlereagh Quarter Sessions, on Tuesday, 24th ult., James Lenaghan, Tournagee, sued Martin Murray, Ballyglass, for damages for breach of warranty of a horse.

Mr. P. C. P. MacDermot was for the plaintiff, and Mr. Staunton defended.

Lanaghan, in reply to Mr. P. C. P. MacDermot, deposed that the animal was not a gelding as he was engaged to be. The animal was bought at £15 15s., and he could not do farm work now with the animal.

Mr. James Watson, v.s., jun., deposed that Lenaghan brought the horse to him in Boyle. The animal was not a gelding.

To Mr. Staunton; I examined the horse carefully. To the best of my knowledge the animal is not a gelding.

Andrew Lenaghan deposed in reply to Mr. P. C. P. MacDermot that the animal was bought at the fair of Ballinagare on Jan. 6th. He said the colt seemed to behave rather unusually.

Mr. Robert Hans deposed he had got a certificate in Science from the Royal Veterinary College. He was now in his final year, and had carried out about fifty such operations each year which were invariably suc-

cessful. He carried out the operation on the animal last April. He swore positively this horse was a gelding.

Mr. P. C. P. MacDermot: When you went to Lenaghan's house why did you not tell him your name?—I did not think it was necessary.

You are a handy man? You are not a vet?—I will be one soon.

It would be a serious thing for you if it went through the country that you did not successfully carry on the operation?—Owners of animals for whom I have carried out such work would not have any other.

Mr. E. Mulligan, v.s., Roscommon, deposed he examined the horse, and in his opinion it was a gelding.

To Mr. P. C. P. MacDermot: I disagree with Mr. Watson when he says the operation was not successfully performed.

How do you account for the horse's actions?—He is a spirited horse.

Martin Murray deposed he sold the gelding to Lenaghan at Ballinagare fair. The colt was the finest one ever he had. The operation was successfully performed.

Mr. P. C. P. MacDermot:—Was it not rather unusual to see a colt of his age?—No.

You engaged the animal to be all right?—Yes.

There is a difference between the "vets." and would you agree to pay the fees of Mr. Vahey, v.s., Sligo, if you are wrong in this?—That depends (laughter).

Thomas Morahan corroborated.

His Honour said he held the colt was a gelding, and he dismissed the action.—*Roscommon Herald*.

Swine Fever.

At a meeting of the Council of the Central and Associated Chambers of Agriculture held on March 31st at the Surveyor's Institute, Mr. C. Bathurst, M.P., was in the chair.

The report of the Cattle Diseases Committee stated that the deputation which waited upon the President of the Board of Agriculture on the subject of the Tuberculosis Order received a most sympathetic hearing. They regretted that the Departmental Committee on Swine Fever (the conclusions of which appeared in *The Times* of February 12) had not been able as yet to come to more definite conclusions on this very difficult question, and were of opinion that it would be more satisfactory to agriculturists if the Departmental Committee were to publish further particulars as to details of the experiments carried out by them.

Professor Penberthy, in moving the adoption of the report, said the deputation to Mr. Runciman took the form of a private conversation. Mr. Runciman was very sympathetic in respect to dual valuation, increased compensation, and the cost of administration, and no doubt this would be evidenced in any new Order issued.

Colonel Lewis said they had been for a good many years trying to stamp out swine fever, but they could not say that all the efforts of the Department of Agriculture had met with even modified success. In the last five or six years nearly half a million had been spent, and the net result was that swine fever had increased enormously. The administrative action taken to stamp out swine fever had been a complete and absolute failure. There seemed, therefore, to be no particular reason why these vexatious restrictions should still be imposed on the agricultural community.

In the course of discussion, the view was expressed that, if pigs were slaughtered at the market and only removed under licence, swine fever would be reduced enormously.

Mr. Wood Homer dissented from the idea that restrictions on swine fever should be abolished.

Mr. Courthope, M.P., Chairman of the Departmental Committee on Swine Fever, said no doubt a carefully thought out adaptation of inoculation treatment in this country might save the Government, and probably County Councils, a good deal of expenditure. It would not, as far as he could see, save the farmers anything. That the Departmental Committee had not been able to come to more definite conclusions was due to the fact that so little was known of the disease. The present orders and administration of swine fever had completely broken down. But if they were to recommend the Board of Agriculture to "scrap" their present system of control the Departmental Committee must do one of two things. They must be prepared to justify the removal of all restrictions and allow swine fever to "rip," or suggest some reasonable proposals for dealing effectively with it in place of the policy of control. He thought the Chamber would be very rash to propose the removal of all restrictions, and it was with a view to finding some means of dealing effectively with the disease that experiments were being carried out, and further experiments were still necessary.

The Chairman said the Board of Agriculture could not stamp out this disease, because a large number of animals affected showed no discoverable symptoms of it, yet they communicated it to the pigs. Therefore, it was impossible to defend the existing harassing restrictions. Other countries were recognising the futility of restriction, and abandoning them in the interests of the pig trade.—The report was adopted.

Mr. R. C. Gray moved "That, owing to the enormous increase of mechanical traction, the whole cost of the maintenance of such roads as are in general use for the purpose of through traffic should be borne by the Imperial Exchequer." He said the roads which formerly cost £15 to £18 per mile to keep up now costs hundreds of pounds per mile. (Carried.)

OBITUARY

THOMAS AUBREY, F.R.C.V.S., Clifton, Bristol.
Graduated, Lond: May, 1854. F. Jan., 1893.

By the death of Mr. Thos. Aubrey, F.R.C.V.S., of Clifton, Bristol, the profession loses one of its oldest practitioners. Passing away on Saturday last quite suddenly from arterio-sclerosis, he was in his 82nd year, and had been in active practice almost half a century. His funeral took place on Tuesday at Bitton, Gloucestershire, and was attended by a representative gathering, including many veterinary surgeons, for he was widely known and very much respected.

He was born in 1833 at Salisbury, and was for 38 years in practice there, until 1892, when he took over the practice at Bath of the late Mr. T. D. Broad, F.R.C.V.S. On retiring in 1904, he was succeeded by Mr. Eve; the business is now in the hands of Mr. J. J. Aveston.

For many years Mr. Aubrey was veterinary surgeon to the Bath and West of England Show, and to the Shire and Hackney Shows in London, as well as others in different parts of England. An excellent judge of shoeing, his services as an adjudicator in this branch were in much demand. In 1876 he married Kate, daughter of T. D. Broad, who survives him, with four sons and four daughters. The former are Dr. Aubrey, of Bitton, and Messrs. Fred, Harold, and Leonard Aubrey, all dental surgeons.

CHARLES RUGG, M.R.C.V.S., late of Marden, Kent.
Lond: April, 1870.

Mr. Rugg's death occurred on 28th March, at a nursing home in Kensington, at the age of 64. He was brother of Mr. George Rugg, M.R.C.V.S. Chiswick, London,

GEORGE CRAIK, M.R.C.V.S., Alnwick.

New, Edin: May, 1888

Mr. Deputy Coroner H. J. Percy held an inquest at the Court House, Alnwick, on Monday, 30th ult., touching the death of Mr. George Craik, M.R.C.V.S., of Nether House, Alnwick, who died from injuries received through the hunter which he rode bolting with him.

George Cockburn Robertson, brother-in-law, gave evidence of identification.

Thomas Davison Hall, steam-roller driver, West Allerdean, who was in charge of a road roller, stated that he was working on the road between the railway station and the Royal Oak. When about 50 yards off Mr. Craik shouted to him to shift his engine to the other side of the road. The engine was then standing. He started the engine, and got across to the other side of the road. Looking back, he saw Mr. Craik lying in the middle of the road, the horse standing about a yard away from him.

Robert Clark, yard foreman at the White Swan posting establishment, said about half-past two o'clock on Friday afternoon, he was driving a pair of horses attached to a carriage along the South Road. Mr. Craik was going along in front of him, and his (Mr. Craik's) horse started to plunge, and jumped on to the cement footpath at the side of the road, where it slipped and fell almost on its hindquarters, but did not go down. Mr. Craik kept his seat. Regaining its feet, Mr. Craik's horse made a jump to come on to the road, but its legs went out from below it and it fell into the road, Mr. Craik being underneath, but he fell on his face.

Dr. Scott Purves stated that he was called to the Infirmary about 2.25 p.m. on Friday, where he saw the deceased, who was not unconscious. There was a bruise on the back of his head caused by coming into contact with the road. By 4 o'clock Mr. Craik had recovered himself, and he (Dr. Purves) got his car and took him from the infirmary to his home. Mr. Craik was able to walk upstairs to his bedroom, where he put him to bed. It subsequently proved that hæmorrhage had been going on, and at 10 o'clock at night, when Dr. Robson was present, Mr. Craik had become unconscious, and was showing signs of concussion of the brain. He and Dr. Robson considered it would be advisable to send for a specialist, and Dr. Richardson arrived about 1.30 a.m., by which time Mr. Craik appeared to be better than earlier in the night, and it was considered that an operation was not necessary.

The Deputy Coroner, after remarking upon the evidence, said the jury, as well as himself, would wish to convey to the widow of their esteemed townsman their deepest sympathy in her sad bereavement.

The jury found that deceased died from cerebral compression, the result of being accidentally thrown from his horse.

The remains of the late Mr. George Craik were laid to rest in the cemetery at Alnwick on Monday afternoon. The procession which followed was a very long one, the late Mr. Craik having been most popular amongst all classes. The cortege was preceded by upwards of seventy of the Masonic brotherhood, of which the late Mr. Craik had been a member. The principal mourners were Mr. Adam Robertson and Mr. G. C. Robertson, Mr. D. Craig, Messrs. D., G., and W. Craik, Mr. Reive, Misses G. and A. Reive, Mr. P. Marshall, Mr. Marshall, jun., Mr. D. Robinson, Mr. Ralph Nesbitt, Mr. James Lillico, Mr. R. F. Robertson, Mr. Adam T. Robertson, and Mr. T. Reavell; Sir Francis E. Walker, representing the Duke of Northumberland and Earl Percy; and Mr. L. R. Pym.

Representing the Percy and neighbouring hunts were Captain R. Milvain, M.F.H., Mr. R. Basil Hoare, M.F.H., Shawdon; Mr. T. Arthur, Bell's Hill; Mr. Rupert S. Wright, Belvedere; Mr. F. O. Chrisp, Prend-

wick; Dr. Fenwick, Longframlington; Captain M. Burrell, Broompark; Captain C. E. Browne, Brunton; Captain M. Browne, Tuggal; Mr. Alex Browne, Callaly Castle; Mr. F. P. Barnett, Whalton; Mr. G. Bolam, Newham Hall; Mr. Wm. Bell, Ratcheugh; Colonel Kenyon-Slaney, Broompark; Mr. M. Whiteford, Warkworth; Mr. John Sordy, Greensfield; Mr. G. Green, Birling; Mr. R. L. Allgood, Titlington; Mr. Beckett Clayhills, Dancing Hall; Mr. J. J. Pawson, Newton Link House; Mr. C. R. Pawson, Callaly; Mr. W. J. Glahome, Littlehoughton; Mr. W. Glahome, Alnwick.

Dr. Clement Stephenson, Mr. G. Elphick, Mr. Davison, Newcastle; Mr. W. Taylor, Morpeth; Mr. Cameron, Berwick; Mr. Lawson, Rothbury; Mr. Lyon, Wooller; represented the veterinary profession.

The committee of the Alnwick Infirmary were represented by Dr. Scott Purves and eleven other members.

The Alnwick Swimming Club, of which Mrs. Craik had been president of the ladies' section, was represented by Messrs. J. Wrightman Douglas, W. A. Hudson, and J. Frater.—*Newcastle Daily Journal*.

JAMES HALL BROWN, M.R.C.V.S., Westcliffe-on-Sea.

London: May, 1861.

Death took place on March 25th from senile decay: cardiac failure. Aged 77 years.

PARLIAMENTARY.

In the House of Commons, on Thursday, March 26th

Mr. HERBERT SAMUEL, in answer to Mr. Astor, said that investigations made on behalf of the Local Government Board indicated that tuberculosis in children was often clearly connected with the consumption of tuberculous milk. He was now engaged in the preparation of legislation to deal with this and other sources of infection and with the adulteration of milk, and hoped to be able to make a statement with regard to it at an early date.

The Tuberculosis Order in Perthshire.

At a meeting of the Perthshire Local Authority, Mr. Wm. Henderson, Lawton, presiding, Mr. Marshall, jun., reported that the Executive Committee appointed by the representatives of Scottish Local Authorities in connection with the proposed amendment of the Tuberculosis Order agreed to ask all Local Authorities for suggestions, and thereafter to have another meeting. There seemed to be a consensus of opinion that the scope of the Order should be extended to cover all cases of animals which, although apparently healthy, were spreading disease germs. The opinion was also strongly expressed that the whole cost of compensation should be borne by the Exchequer.

The meeting then proceeded to consider *seriatim* the proposals sent out by the Executive. The first was that the veterinary inspector be empowered to employ the tuberculin test without the consent of the owner. After consideration, the suggestion was approved.

The second suggestion was that Article B (1) be deleted, or (2) amended to meet the difficulties which have arisen in practice. The Chairman said that this referred to the removal of suspected cases in markets and sale yards for examination. Certain Local Authorities had been involved in serious questions. The Executive's proposal was agreed to.

The third proposal was that the scope of the Order be widened to include all bovine animals actively disseminating the germs of tuberculosis. Mr. Ferguson said that what they had to fight against was the man who tied up a pinner in the stalls on a Friday and was followed by a man who tied up a clean beast on Monday. It was

agreed to approve of the extension of the Order as suggested.

The fourth suggestion, which was also approved of, was that a request be made that the whole cost of administration, including compensation paid, be borne out of imperial funds, or, alternatively, that a request be made that in addition to part of the compensation being paid out of imperial funds, the cost of administration be borne out of this source.

Mr. Marshall reported that the number of tuberculosis cases notified to date was 53. Of these, 9 were not confirmed, 1 not examined, and 1 was still under consideration. As the result of post-mortem examination, only 1 out of the 42 was not confirmed. Of the cases, 6 were not advanced and 35 advanced. The compensation paid or payable was £120, salvage received, £25 14s. 9d., and administration expenses ran to £2 10s. per case.—*Scottish Farmer*.

Foot-and-Mouth Disease.

An outbreak of foot-and-mouth disease has occurred at Ticknock, Co. Dublin, and movements of animals in the district, including the City of Dublin, have been prohibited.

Animal Diseases in Edinburgh.

A report by Professor Dewar, the veterinary inspector on the work in connection with the Diseases of Animals Acts in Edinburgh for the year 1913, was submitted at a meeting of Edinburgh magistrates held recently. It stated that there had been but one outbreak of swine fever reported as having occurred within the city during the year, though a serious outbreak occurred in the Corstorphine district in the early summer, which entailed a good deal of extra work in connection with the markets. Not for over two years had a case of anthrax come under Prof. Dewar's notice as having occurred within the boundary, but quite a number of suspected cases had been reported. There was only one case of glanders; and although a large number of sheep passed through their markets during the year, there were no cases of sheep scab. Referring to foot-and-mouth disease, he said that notwithstanding the fact that numerous complaints had been made that the twelve hours which the Board of Agriculture claimed was necessary for inspection was a hindrance to trade, it had been continued to the end of the year. Only six outbreaks of parasitic mange were reported, and four of these were confined to single animals. Four tuberculous cows in dairy byres were destroyed. The authority's experience of the Tuberculosis Order of 1913 helped to give them more confidence, as they found the compensation to be made comparatively small.—*N.B.A.*

Mr. Rockefeller and Animal Diseases.

Mr. John D. Rockefeller, according to an announcement made recently, has given £200,000 to the Rockefeller Institute for Medical Research, to be used to organise and conduct a department for the study of animal diseases.

Hitherto the Rockefeller Institute has confined its investigations to studies of the fundamental problems of biological science, and to the field of human diseases. From the economic standpoint Mr. Rockefeller's gift will go far, it is believed, to minimise the great annual loss to the country entailed by animal disease. Such losses discourage enterprise in animal husbandry, and consequently increase the cost of living. Last year, it is estimated, an epidemic of hog cholera killed £12,000,000 worth of swine in the North-West alone.

MERCK'S ANNUAL REPORT OF RECENT ADVANCES IN PHARMACEUTICAL CHEMISTRY AND THERAPEUTICS. 1912. Vol. XXVI (E. Merck, Chemical Works, Darmstadt, 1913. London office, 16 Jewry Street, E.C.)

Merck's Annual Report is always welcomed by pharmacists and physicians alike, as an invaluable summary of the recent progress of their closely allied sciences. The work is so well-known that all we need do is to indicate two special features in the present volume, and to add that it more than maintains the standard set by its twenty-five predecessors. The special features are a long commencing article (physiological, chemical, and therapeutical) upon lecithin, and a shorter one as an appendix (by Prof. R. Heinz) on the assay and standardisation of digitalis preparations. The bulk of the volume is made up as usual—by a series of articles upon all drugs known to the editor which have been the subject of advances since the publication of the last volume. These include many little-known agents, and many others—such as eucalyptus oil, salicylic acid, and sodium bicarbonate and thiosulphate, which are used by almost every practitioner. The whole is as interesting and suggestive as we have been accustomed to find Merck's Report in previous years; and as veterinary medicine, if not very prominent in its pages, is by no means neglected, it should find many readers in our profession.

W. R. C.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, March 27.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Regiments or Corps

ARMY VETERINARY CORPS.

J. J. Mills, late Cadet-Serg. Royal Vety. Coll. of Ireland O.T.C., to be Lieut. (on probation). Dated March 28.

Prohibition of Export of Russian Horses.

The Bill prohibiting the export of Russian horses abroad came into force last week. The main object of the measure is to lower the cost of cavalry remounts for the Russian Army. During the last few years the Germans have bought 100,000 horses in Russia annually, with the result that prices in this country have risen inordinately.—*Reuter*.

Personal.

Mr. WILLIAM MARSHALL, M.R.C.V.S., Aberdeen, has been recommended to the Council for appointment as veterinary surgeon for the city by a joint meeting of members of the Bills and Law, Public Health, and Cleansing Committees of the Aberdeen Town Council

Mr. ANDREW MACGREGOR, M.R.C.V.S., of Glengyle, Comrie Road, Crieff, N.B., farmer, at The Currochs, Monrievaird, and for a period in the Irrawaddy Flotilla Service, left estate of the gross value of £11,476.

Principal McCALL, F.R.C.V.S., and Mr. ANDREW ROBB, F.R.C.V.S., together with the local inspector appointed by the Highland and Agricultural Society, have been appointed veterinary inspectors for the Cawdor Cup Competition at the show at Hawick.

TRANSMISSIBILITY OF TUBERCULOSIS.

Dear Sir,

The *Veterinary Record* of March 21st contains a letter of admonition from Mr. Coleman to Mr. Harold Leeney for daring to support Mr. R. Mond's views on Tuberculosis, and incidentally he tries to belittle Mr. Mond by stating that he is the son of a chemist who has made a lot of money. This forcibly reminds me of the old saying "If you have a bad case abuse your opponent," but that is no argument. Mr. Mond is a worthy and able son of a very able father, and uses his wealth for the advancement of science and the benefit of his fellow creatures. He runs a hospital for infants in London, which is under the intensely keen supervision of Ralph Vincent, M.D. It is from the feeding of a very large number of infants at this institution that Mr. Mond's deductions are chiefly drawn.

I think it would be impossible to find two more unremitting in their efforts to get at the unvarnished truth on this subject than Mr. R. Mond and Dr. Vincent, and we ought not to object to new light, from whatever source, on this terrible scourge. There is yet a great deal to learn about tuberculosis and tuberculin with its uses and abuses. It is only by an honest receptivity of mind, and a willingness to throw off preconceived ideas, that our small profession has been enabled to make such rapid advancement of late years.

D. PUGH, F.R.C.V.S.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1344.

APRIL 11, 1914.

VOL. XXVI.

THE COUNCIL MEETING.

Little need be said of last week's Council meeting. The matter which occasioned most debate was the still unsettled question of the preliminary examination, which has recurred constantly at recent meetings. Some of the discussion that took place upon this might well have been deferred till the July meeting, when the question will be finally decided. Further, it cannot be said that the discussion was very enlightening. Perhaps the clearest utterances came from Sir John M'Fadyean, in moving the adoption of the Preliminary Examination Committee's report, but even he showed a little less than his usual lucidity.

We gather that the Committee proposes to leave our matriculation standard unaltered, while authorising two educational bodies to conduct a "special" examination for intending veterinary students, and we can only infer that the examination will have to be carried on "specially" for us because we are ceasing to have a common standard with the medical profession. But the whole subject might have been made clearer—and ought to have been, considering the time spent in discussing it.

Apparently it is proposed to alter our matriculation syllabus in one respect. Two languages will still be required, but Latin will no longer be a compulsory subject. This is a rather important change, and there is something to be said both for and against it.

Very little else in the report calls for notice. Our Charter, not being dependent upon Parliamentary chances, is making good progress. But, unfortunately, it has been found advisable to spend no more money this Session in trying to push our Bill. The hopeless position of the Bill at present justifies the decision. But meanwhile the fact that the Treasurer has been authorised to sell another £1000 worth of Consols shows how sorely the measure is needed.

THE INTERNATIONAL VETERINARY CONGRESS.

Great progress has been made in every direction during the last few weeks with regard to this Congress. The arrangements for the meetings and subsequent tour are now far advanced, and dona-

tions have lately been coming in well. At present there is every indication that the Congress will be a successful one. But the time is now drawing near—the Congress will be over four months hence—and those who intend to subscribe, and have not yet done so, should delay no longer. New donations to the Fund will still be welcome, and all promised ones should now be regarded as due.

THE "ARMAGH DISEASE."

The 1912 outbreak of foot-and-mouth disease in Ireland brought to light what seems to be a new form of bovine stomatitis. It is mentioned in the English Board of Agriculture's 1912 veterinary report, and is dealt with at much greater length in the special report upon foot-and-mouth disease in 1912 issued by the Irish Department. When first noticed during the rigorous inspections of 1912, its lesions were suspected to be old ones of foot-and-mouth disease; and there was some difference of opinion on this point between the Irish and English authorities. Eventually the disease was traced back to Armagh; a farm was found with cattle showing it in various stages; and here it was definitely ascertained that the condition was not foot-and-mouth disease. Subsequently the disease was investigated by Prof. Mettam, whose results are published in the Irish Departmental report.

The disease is contagious amongst cattle—especially young ones—but is not transmitted to sheep and pigs. The lesions are confined to the mucous membrane of the mouth—the lips, tongue, and dental pad. They consist essentially in a very superficial loss of epithelium over areas of varying size and shape, which tend to extend and coalesce.

The only portion of the tongue affected is that bearing horny papillæ, which are completely removed, leaving the tongue like that of a newly-born calf. The loss of epithelium, however, is never deep enough to cause trouble. There is no vesiculation, no salivation or soreness of the mouth, and no disturbance of temperature, appetite, or rumination. The animal is in normal health to all appearance, and the condition is only detected by opening and examining the mouth.

So far, attempts to isolate a causal organism have been unsuccessful. The disease is a mild one, and veterinary surgeons are seldom or never asked to treat it. But it has a certain importance on one account—experience has shown that it is possible to mistake an isolated case for one of foot-and-mouth disease; for that reason it is well to remember that such a condition exists so near to us, and Prof. Mettam's account of it in the Irish report is worth reading.

THE EFFECT OF AN INJECTION OF MALLEIN ON THE SERUM DIAGNOSIS OF GLANDERS.

By BASIL BUXTON, F.R.C.V.S.

Since the discovery of the causal organism of glanders by Loeffler and Schutz in 1883, numerous attempts at an improvement in the methods of diagnosis have been made.

The only method originally available consisted in the isolation of the infective agent, and was confined to the demonstration and cultivation of the organism. Later it was found possible to reproduce the disease by inoculation of infected material into susceptible animals, and this method of diagnosis still persists, the guinea-pig being perhaps the most suitable animal for the purpose, and the characteristic reaction first described by Straus being regarded as diagnostic of the disease.

The most important agent, however, in the diagnosis of glanders was the biological product of the bacillus mallei, generally known as mallein. The method of preparation of this agent, and its efficacy are well known, and while numerous veterinarians on the Continent are dubious as to its general utility, clinicians in this country appear to have obtained more satisfactory results. It is certain that without the aid of mallein it would have been impossible to have reduced the occurrence of glanders to the state which now exists.

Based upon the ophthalmic reaction for tuberculosis, Frohner (11) carried out a number of experiments with precipitated mallein in the case of glandered horses and numerous healthy controls. As a result of his observations he came to the conclusion that the ophthalmic test was superior to either the subcutaneous or cuti reactions, and urged that it should become a routine method of diagnosis.

There are, however, some cases in which the efficiency of mallein as a diagnostic agent cannot be entirely relied upon, namely, those instances in which an atypical reaction is obtained on more than one occasion in the same animal. It is in such cases that the methods of serum diagnosis have been specially advocated. The most important of these methods are the agglutination and complement binding tests.

The agglutination test as a means of diagnosing glanders was first suggested by M'Fadyean in 1896, but was not generally adopted until the method was perfected by Schutz and Miessner, whose results were published in 1905 (12). It has since been employed in practically every country where glanders exists, and ample opportunity has, therefore, been furnished for observing its practical diagnostic value.

While there is no doubt that the agglutination test is of great value in cases of recent infection and of a virulent type, the blood in such cases showing an agglutinating titre of 1-1000 or higher, experi-

ence has shown that in the case of chronic glanders an agglutinating titre as low as that of normal horses (1-400) is frequently encountered, while on the other hand cases have been recorded in which the agglutinating titre of normal serum has been found to be as high as 1-800 and further, where the curve has been followed for some time, variations have been exhibited in the titre of normal horses.

As a result of the important researches of Bordet and Gengou concerning the phenomenon of hæmolysis, and the subsequent investigations of Ehrlich, Morgenroth, Sachs and others, it was found to be possible to apply an even more delicate test to the diagnosis of glanders—the "Complement Fixation" test, which was first suggested in this connection by Schutz and Schubert (2) in 1909. Hutyra and Marek (4) concluded, as a result of numerous tests carried out by them in 1910, that "the diagnosis of glanders by the complement fixation test has already given such accurate results that it may be considered as the best method for the determination of this disease at the present time." In 1911 Moller and Eichhorn (3) published the results of an extensive series of experiments carried out by them, in which the superiority of the complement fixation test over other known methods of diagnosis was amply demonstrated.

While nobody has apparently doubted the specificity of the methods of serum diagnosis for glanders when such constituted the primary test, yet recently it has been stated by various investigators that a previous injection of mallein rendered the serum tests unreliable, since as a result of the mallein injection, both agglutinating and complement binding antibodies were produced far in excess of those normally present in the blood of healthy horses. While it was well known subsequent to the work of Pokschischewsky and Fedorowsky (5) that an injection of mallein produced a marked increase in the production of these specific antibodies in animals affected with glanders, either by natural or artificial means, it was not recognised until recently that such a stimulation occurred in the case of non-infected animals.

In the latter case some doubt appears to exist concerning the time at which such a production of antibodies occurs, and the period over which the high titre is maintained. Bonome (6) was of opinion that the high agglutinating titre exhibited by such treated animals did not last for more than 5 to 7 days, and Arpad (7) showed that an agglutinating titre of 1-1200 to 1-1600 began to fall after 7 days. Miessner (8) found that the agglutinating titre began to rise in from 5 to 7 days after the injection of mallein, the maximum being attained towards the end of the second week, while the normal was regained in from 4 to 6 weeks. Arpad Marcis (9), as a result of experiments carried out on two animals, a stallion and a foal, came to the conclusion that after an injection of 5 cc. mallein there was a production of agglutinating and complement binding antibodies far in excess of the normal. He was able to demonstrate an increase in the former in from 5 to 7 days, and in the latter in from 6 to 10 days after the mallein injection, and

* Read at the meeting of the Central V.S., held at 10 Red Lion Square, W.C., on Thursday, April 2nd.

found that the titre in each case began to fall in from 2 to 3 weeks, and in 3 months had regained the normal. Mohler and Eichhorn (10), on the other hand, are of the opinion that the immune bodies produced as a result of the stimulation of the mallein injection will have disappeared in from 7 to 10 days.

There seems, therefore, to be some doubt concerning the period over which this excess of immune bodies persists, and also the time at which the increase begins. The following experiments have been carried out with a view to acquiring a more exact knowledge of these facts.

The following is a brief description of the technique employed in carrying out the tests.

TECHNIQUE OF THE AGGLUTINATION TEST.

The antigen consisted of a saline suspension of *B. mallei* of a standard concentration, the organism being obtained from a 24 hours old surface culture on agar or blood agar.

The blood to be tested was obtained in the ordinary way from the jugular vein in the case of the larger animals, and from the ear veins in the case of the smaller laboratory animals.

The blood (2-3 c.c.) was collected in test tubes, which were placed in the incubator or water bath at 37° C. in a slanting position until the serum had separated off.

In the routine examination the following dilutions of serum were employed:—1:125, 1:200, 1:250, 1:400, 1:500, 1:750, and 1:1000.

If the blood from several animals was being tested, the pipette was thoroughly washed between each sample, and was always rinsed out with saline between each dilution, in order to avoid any abnormal results in the higher dilutions consequent upon a trace of serum having been left in the pipette.

The dilutions having been made, 1 c.c. of antigen was added to each tube, followed by 1 c.c. of the diluted serum. The tubes were then well shaken and incubated overnight at 37° C. In recording the results of the agglutination test, if the last tube containing 1/1000 c.c. of serum showed complete agglutination, the titre was said to be less than 1/2000. If the last tube showed nearly complete agglutination, the titre was recorded as equal to 1/2000. If the last tube showed only a trace of agglutination, while the next to the last showed complete clumping, the titre was said to be equal to 1/1500.

TECHNIQUE OF THE COMPLEMENT FIXATION TEST.

The following reagents were employed in the quantities stated:

- (a) The serum to be tested.
- (b) The complement 0.05 c.c., *i.e.* 0.5 c.c. of a 1 in 10 dilution.
- (c) The antigen 0.5 c.c. of required concentration.
- (d) The hæmolysin 0.001 c.c., *i.e.* 0.5 c.c. of a 1 in 500 dilution.
- (e) The red cells (sheep) 0.5 c.c. of a 5 per cent. suspension.

The proportions recommended by Surface were also employed to control the results obtained with the above system, *viz.*:

- (a)
- (b) 1.5 times amount required to produce hæmolysis.
- (c) As required.
- (d) 0.25 c.c. of a 1 in 50 dilution (5 times amount required to produce hæmolysis).
- (e) 0.5 c.c. of a 2 per cent. suspension.
- (a) The serum was obtained in the same manner as for the agglutination test, and the following routine dilutions were employed: 0.3, 0.2, 0.1, 0.05, 0.02, 0.01.

(b) The complement consisted of fresh guinea-pig serum suitably diluted.

(c) The antigen consisted of either a saline suspension of *B. mallei*, which had been killed by heating for 1 hour at 60° C., or a solution of precipitated mallein, and in some cases the antigen was prepared by dissolving the bacterial cells in a 10 per cent. solution of anti-formin. The dissolved bacterial substance was then precipitated with alcohol, separated by centrifuging and suspended in saline solution. A fourth method of preparing the antigen was to *alternately* freeze and thaw a suspension of the organisms, the mixture being well shaken between each thawing and subsequent freezing.

The amount of antigen employed in each case was one-half the quantity required to produce self deviation, *i.e.* to absorb the amount of complement used.

(d) The hæmolysin was horse serum sensitised by sheeps red cells, and possessing a hæmolytic titre of 0.001.

(e) The second antigen—sheeps red cells were obtained in the ordinary way, and had been washed three times in normal saline solution.

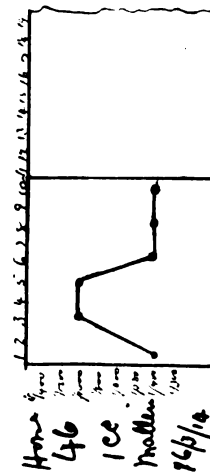

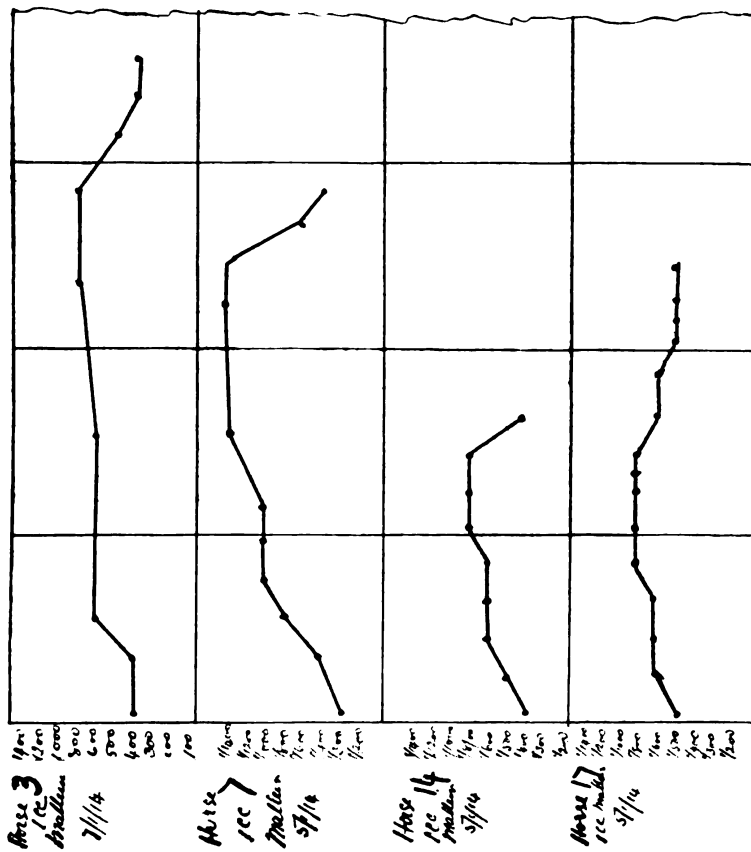

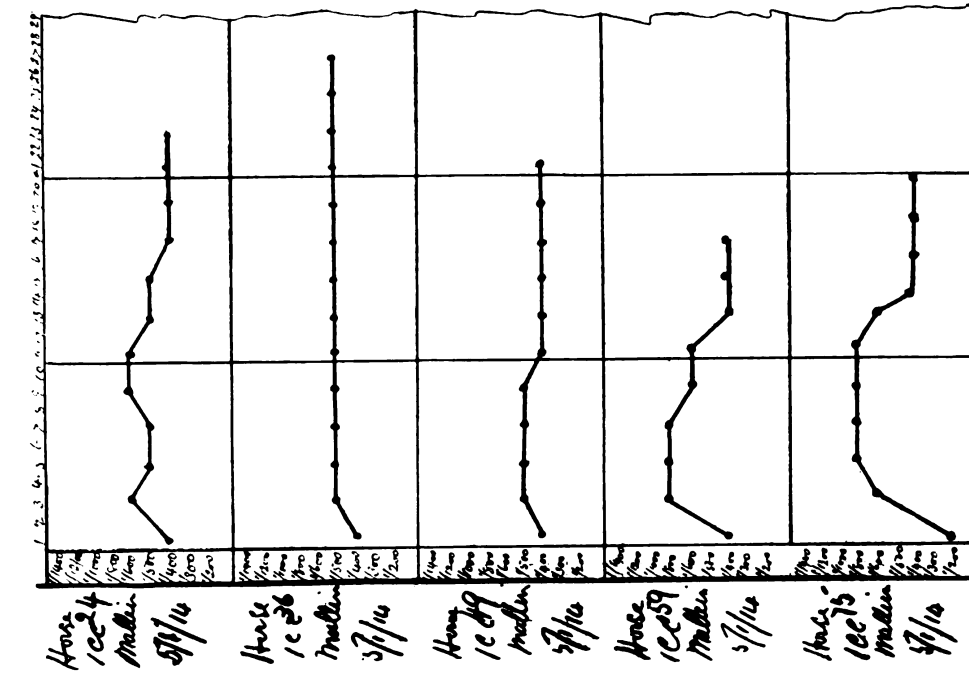

All reagents were titrated before use.

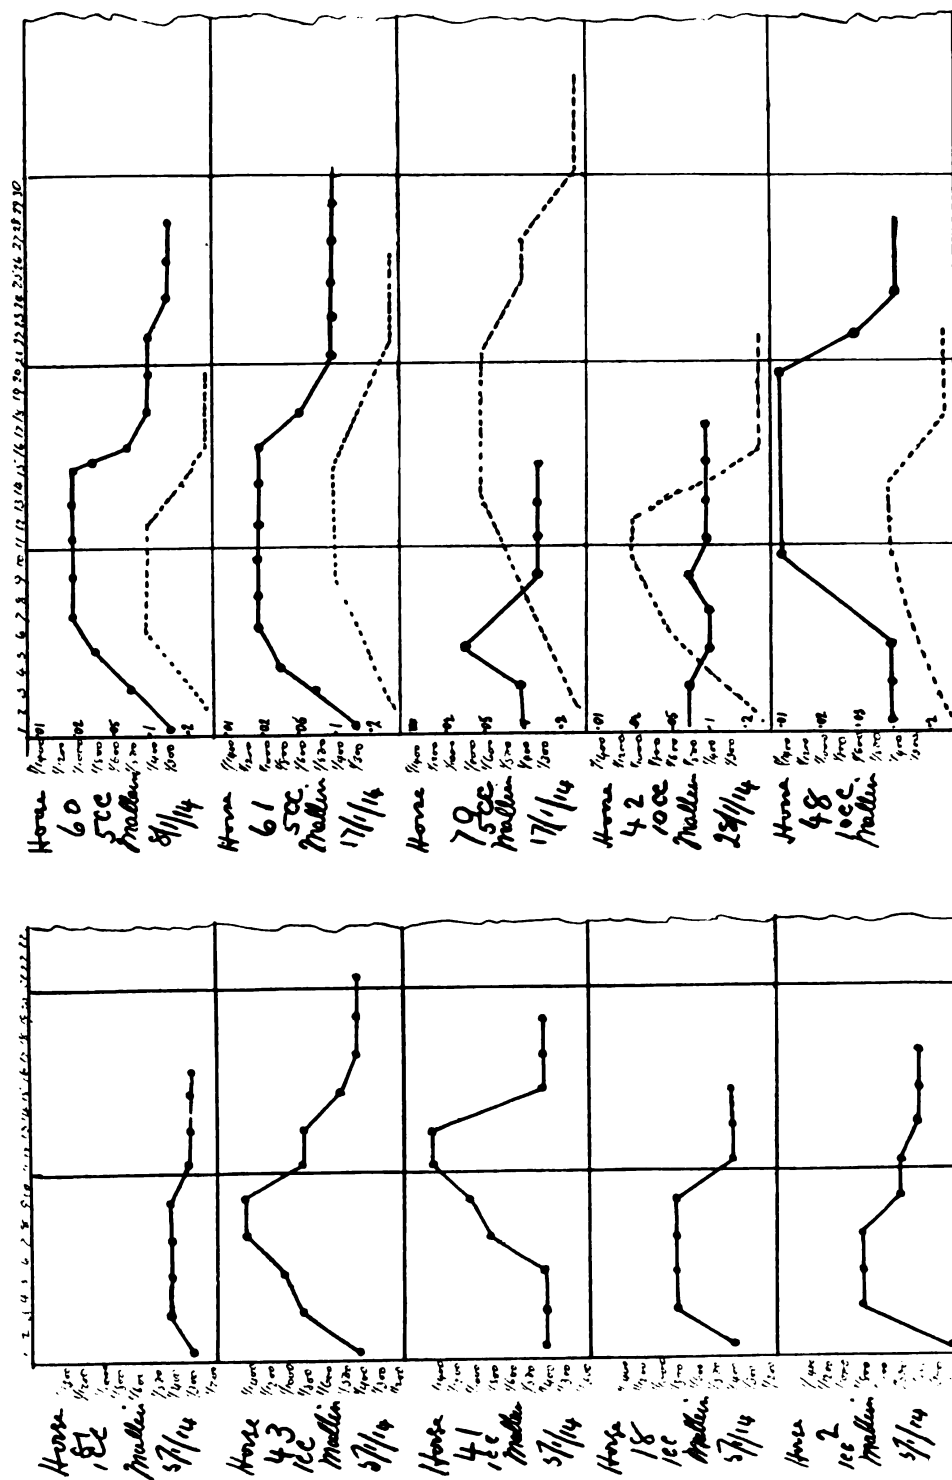

A water bath at 40° C. was used in place of the thermostat at 37° C., a considerable saving in time being in this way effected, since the results could be read at the end of 20 minutes instead of one hour. Control experiments were also carried out, in which the water bath was used at 37° C. for one hour.

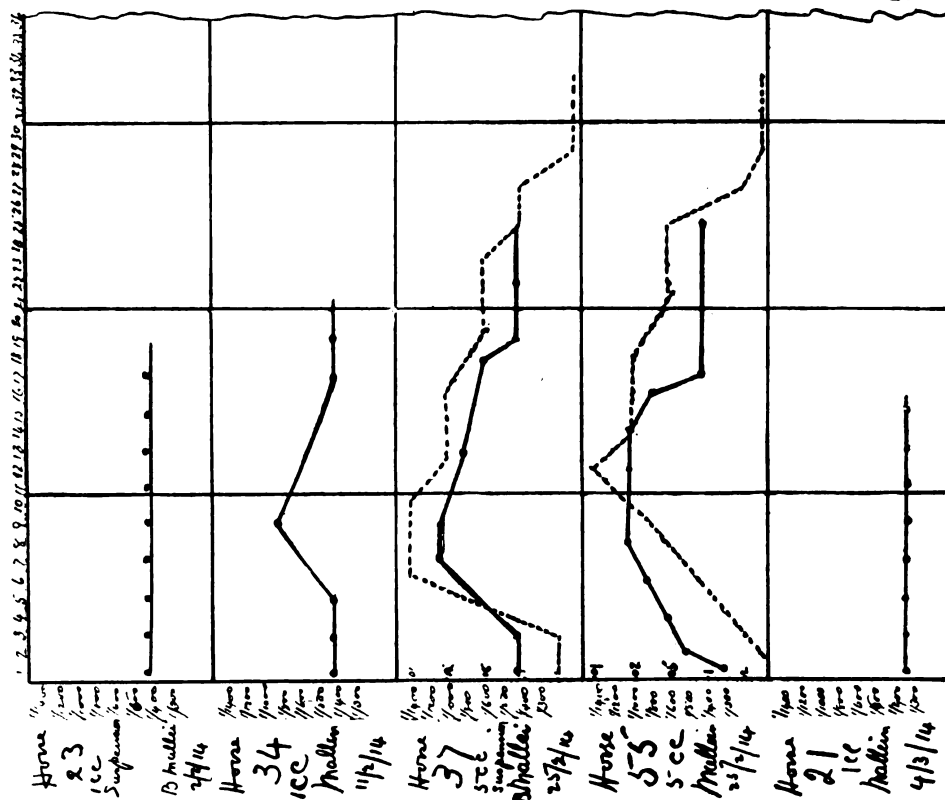

The test was put up in the ordinary manner. Into each of a number of clean bacteriological test tubes was placed 0.5 c.c. of a 0.9 per cent. saline solution, followed by the required amount of antigen (ascertained from the titration of the antigen). 0.5 c.c. of a 1/10 complement was then added, followed by varying dilutions of the serum which it was required to examine, and which had previously been inactivated by heating for 1 hour at 56° C.

At the same time control tubes were put up containing all the constituents with the exception of the serum to be tested.

The tubes were then agitated to thoroughly mix the contents, and were left in the water bath at 40° C. for 20 minutes. At the end of that time, 0.5 c.c. of a 1/500 inactivated hæmolytic serum was added, and 0.5 c.c. of a 5 per cent. suspension of sheeps red cells. The tubes were again agitated,

and left for a further 20 minutes, when the readings were taken. The highest dilution showing no hæmolysis was taken as representing the complement binding titre of that serum.

AGGLUTINATION EXPERIMENTS.

In all 74 horses were used for these experiments. Of these 47 were being immunised against various bacteria or toxins, and with only two exceptions the results obtained with the blood of these horses were similar to those obtained with the blood of the remaining 27 normal horses. For the purpose of this paper it is sufficient if I confine my remarks to the results obtained with the latter. In all these experiments 1 c.c. mallein is equivalent to 0.1 c.c. concentrated mallein, and the normal agglutinating titre varied from 1/100 to 1/500.

Horse 3 received 1 c.c. mallein—normal titre 1/400. No rise was shown until the 6th day, when the titre was 1/600. From the 6th until the 23rd day, no variation was noticed, but from then until the 28th day the titre was 1/800, whence it fell steadily until on the 33rd day it had again reached the normal, which was maintained.

Horse 7 received a similar dose, but showed a quite different curve. Normal titre 1/300. 4th day 1/400, 6th day 1/800, 8th day 1/1000, with a steady rise until the 15th day, when it was found to be 1/1400. This titre was maintained until the 25th day, after which it fell steadily until the 29th day, when the normal was regained.

Horse 14 received 1 c.c. mallein. On the 5th day the titre had risen from 1/400 to 1/600; on the

11th day it had reached 1/800, where it remained until the 15th day, after which it fell sharply to 1/400 on the 17th day.

Horse 17. Normal titre 1/500, received 1 c.c. mallein. On the third day the titre was 1,600, the next rise being on the 9th day, when it had reached 1/800. On the 16th day it had fallen to 1/600, and on the 21st day to 1/400.

Horse 24. Normal titre 1/400, received 1 c.c. mallein, and showed a rather peculiar curve. On the 3rd day the titre had risen to 1/600; on the 5th it fell to 1/400—rose again on the 9th to 1/600, and fell again on the 13th to 1/400, which was maintained.

Horse 36. Normal titre 1/400, received a similar dose to the above. On the 3rd day the titre rose to 1/500, and remained constant for 27 days.

Horse 49 received 1 c.c. mallein. The titre rose from 1/400 to 1/500 on the 3rd day, and returned to 1/400 on the 11th day.

Horse 59. Titre rose from 1/400 to 1/800 on the 3rd day, fell to 1/600 on the 9th day, and to 1/400 on the 17th day.

Horse 75. 1 c.c. mallein. Titre rose from 1/200 to 1/800 on the 5th day, fell on the 11th day to 1/600, and on the 13th day to the normal.

Horse 81 received 1 c.c. mallein. The titre rose from 1/300 to 1/400 on the third day, remained constant until the 9th day, and again fell to 1/300.

Horses 43 and 41 each received 1 c.c. of mallein. In the case of the former the titre rose sharply to 1/1400, which was reached on the 7th day, while that of horse 41 showed no rise until the 5th day,

when the titre began to rise sharply to 1/1400, which was reached on the 11th day. In the case of horse 41 there was a drop from 1/1400 to 1/400 in three days, while the titre of horse 43 fell more gradually, and did not reach the normal until the 17th day.

Horses 18 and 2 each received 1 c.c. of mallein, and in each case the titre rose to 1/800 only, and had regained the normal on the 11th and 9th days respectively.

Horses 60, 61, and 79 each received 5 c.c. mallein. The titre of the first rose from 1/300 to 1/1000 on the 7th day, began to fall from the 15th day, and had regained his normal by the 24th day. That of the second horse showed a very similar curve, but remained at 1/1000 for two days longer than in the case of horse 60.

The titre of horse 79 rose on the 3rd day from 1/400 to 1/600, and immediately began to fall, 1/300 being reached on the 9th day.

Horses 42 and 48. Received 10 c.c. of mallein each, and while in the case of the former there was no rise in the agglutinating titre shown, that of the latter rose from 1/400 to 1/1400 on the 5th day, remained constant until the 19th day, and fell sharply to the normal, which was reached on the 25th day.

Horse 23 received 1 c.c. of a saline suspension of killed *B. mallei* subcutaneously. No rise in the agglutinating titre was shown, however.

Horse 37 received 5 c.c. of the same suspension as horse 23. The agglutinating titre rose from 1/400 to 1/1000 between the 3rd and 7th days, whence it gradually fell, until the normal was reached on the 19th day.

Horse 55 received 5 c.c. of mallein and showed a curve which resembled very closely that of horse 37.

Horses 34, 21, 46 each received 1 c.c. of mallein. The first rose on the 5th day from 1/400 to 1/800, and fell gradually to the normal, which was reached on the 17th day.

Horse 21 showed no titre, while that of horse 46 rose on the 3rd day from 1/400 to 1/1000, and between the 5th and 7th days fell again to the normal.

Horses 57, and 58 each received 1 c.c. of mallein. The normal agglutinating titres were 1/200 and 1/300 respectively, and no rise in titre was produced.

Horses 38 and 33 each received 5 c.c. of glycerine broth, there was, however, no increase in the agglutinins.

Two cows, 1 sheep, 1 goat, 1 dog, 4 rabbits, and 6 guinea-pigs each received 1 c.c. of mallein. In no instance, however, was it possible to demonstrate an agglutinating titre for *B. mallei*.

Two rabbits and 2 guinea-pigs infected with living *B. mallei* gave the following titres: 1/400, 1/1600, 1/1000, and 1/400 respectively.

COMPLEMENT FIXATION EXPERIMENTS.

The blood of all these horses was examined for complement binding properties on alternate days, beginning on the day following the injection of mallein.

Horses 3, 7, 14, 24, 36, 49, 59, 75, 81, 43, 41, 18, 2, 34, 21, 57, 58, and 46, all of which received 1 c.c. of mallein, at no time showed any complement binding titre to any of the antigens employed.

Horses 60, 61, 79, and 55, each of which received 5 c.c. of mallein gave complement binding titres of 0.1, 0.1, 0.05, 0.01 respectively, but only when mallein was used as the antigen. In no case was any titre shown with an antigen prepared from the actual organisms.

Similar results were obtained with the blood of horses 42 and 48, which received 10 c.c. of mallein each, the complement binding titre to mallein being 0.1 and 0.02 respectively.

Horse 23 which received 1 c.c. of a saline suspension of *B. mallei* did not show a titre with any of the antigens.

Horse 37, however, which received 5 c.c. of the above suspension gave a titre of 0.01 when mallein was employed as the antigen, but not in the presence of any preparation of *B. mallei*.

Horse 38 which received 5 c.c. of glycerine broth did not give any titre to either *B. mallei*, or mallein.

Neither the cow, sheep, goat nor dog gave any complement binding titre to any of the antigens employed. The rabbits and guinea-pigs, however, which had received an injection of mallein showed in the presence of mallein as the antigen, titres varying from 0.1 to 0.02.

The two rabbits and two guinea-pigs suffering from glanders gave the following titres:—

		B. mallei			Mallein
		Suspension	Anti-formin	Frozen & thawed	
Rabbit	(a)	0.01	0.01	0.01	0.02
"	(b)	0.01	0.01	0.02	0.02
Guinea-pig	(a)	0.05	0.05	0.05	0.05
"	(b)	0.1	0.1	0.1	Nil

SUMMARY.

Of the 27 normal horses used in these experiments, 19 received a subcutaneous injection of 1 c.c. of mallein. In three only was the agglutinating titre as high as 1/1400; in one it reached 1/1000; in eight 1/800; in one 1/600; in two 1/200; and four showed no titre.

In the case of the 47 horses which were being immunised against various organisms or toxins, four only gave a titre of 1/100; eleven gave 1/800; and the remaining 32 gave titres which varied from 1/300 to 1/600. Of the animals other than horses which received 1 c.c. of mallein, none showed any agglutinating titre to *B. mallei*, while the two rabbits and two guinea-pigs suffering from glanders gave titres varying from 1/400 to 1/1600 to that organism.

The 19 normal horses which received 1 c.c. of mallein failed to show any complement binding titre in the presence of any of the antigens employed. The same result was obtained in the case of 45 of the 47 horses which were being immunised against various organisms or toxins. The two exceptions were horses being immunised

against gonococcus and meningococcus, each of which gave a titre of 0.1 in the presence of *B. mallei*, but not with mallein as the antigen.

The four horses which received 5 c.c. of mallein, and the two which received 10 c.c. showed complement binding titres to mallein varying from 0.1 to 0.01. Those which received 10 c.c. did not show a higher titre than that which was produced in other horses which received 5 c.c.

In two horses which received 5 c.c. of glycerine broth did not show complement binding titres to either *B. mallei* or mallein.

While the blood of animals, other than horses, which had received 1 c.c. mallein showed no complement binding titre to any of the antigens employed, that of rabbits and guinea-pigs suffering from glanders gave titres varying from 0.1 to 0.01 with the various antigens, and in only one case was a negative result obtained.

A peculiar feature of these experiments was the fact that while the horse which received 1 c.c. of a saline suspension of killed *B. mallei* gave no complement binding titre—the blood of that which received 5 c.c. of suspension gave a marked titre to mallein, but none to *B. mallei*.

In neither the agglutination test nor the complement fixation test was it possible to fix definitely the time at which the titre rose and fell. In the former case it was found to begin to rise between the first and fifth day, and to fall between the fifth and 33rd day, while the complement binding titre began to rise from the first to the 14th day and to fall between the 14th and 31st day,

CONCLUSIONS.

From these experiments it would seem that a subcutaneous injection of 1 c.c. mallein is capable of stimulating in some horses the production of agglutinating antibodies specific for *B. mallei*, and that such a production may take place in from 24

hours to five days after such an injection, and may persist for 33 days, or even longer. If, therefore, it is required to carry out agglutination tests for glanders, the blood should be obtained either before the injection of mallein or not less than one month after.

Since the injection of 1 c.c. of mallein does not appear to stimulate the production of complement binding antibodies specific for *B. mallei*, there does not seem to be any objection to such a test being applied at any time irrespective of the period which may have elapsed since the injection of mallein.

Royal College of Veterinary Surgeons.

QUARTERLY MEETING OF COUNCIL.

A quarterly meeting of the Council was held on Friday, 3rd April, at 10 Red Lion Square, London, W.C. Mr. J. H. Carter (President) occupied the chair, and the following members were present: Maj.-General Pringle, Maj. General Thomson, C.B., Professors Bradley, Sir John M'Fadyean, Mettam, Share-Jones, and Shave; Messrs. Abson, Banham, Barrett, Clarkson, Dunstan, Garnett, Mason, McI. McCall, Mulvey, Packman, Price, Slocock, Sir Stewart Stockman, Sumner, and Trigger. Mr. George Thatcher (Solicitor), and Mr. Fred Bullock (Secretary).

MINUTES.

The minutes of the last quarterly meeting were taken as read and confirmed.

OBITUARY.

The SECRETARY read the Obituary List.

ADMISSIONS TO MEMBERSHIP.

The SECRETARY announced that Mr. W. B. Howe had been admitted as a member of the College since the previous quarterly meeting of Council.

CORRESPONDENCE.

The SECRETARY announced that letters regretting their inability to attend the meeting had been received from Principal McCall, Messrs. Lawson, McKinna, and Wharam.

The Secretary read the following letter: "Jan. 12, 1914. Dear Mr. Bullock, I have just received your letter, and wish to thank you for the kind expression of sympathy contained therein; and will you convey to the Council the appreciation of both myself and my brother of all the kind things you have said on behalf of my dearly beloved father.—Yours sincerely (Signed) LOUIE HUNTING."

The Secretary read the following letter: "Jan. 24 1914. To the President and members of the Council, R.C.V.S. Gentlemen, on behalf of my brothers, sisters, and myself, I beg to thank you for the resolution of sympathy in our loss, passed at your last meeting. We also feel very touched at the kindly words expressed by Messrs. Mulvey and Mr. Trigger as reported in last week's *Veterinary Record*. My late father up to the last always took a keen interest in the welfare of the profession, and we, his sons, who follow the same calling, are specially gratified at your expressions of respect to his memory. Yours faithfully, A. C. WILSON. Capt. A.V.C. (Ret.)"

The Secretary read the following letter from the Royal Institute of Public Health: "I am desired by the Council to inform you that the Annual Congress of the Institute will be held this year, on the invitation of the Right Honourable the Lord Provost and the City Council of Edinburgh, in the University of Edinburgh. It has been suggested that it would be agreeable to many veterinary surgeons if a section of the Congress were devoted to Veterinary Hygiene and Pathology. The Council are willing to make arrangements for such a section if the suggestion commends itself to the Council of the Royal College of Veterinary Surgeons, and its organisation can be undertaken by the Council of your College, or by such officials of the section as may be nominated for this purpose and whose appointment the Institute will confirm."

Accompanying the letter was a preliminary programme of the Congress, which takes place from July 15th to July 20th next.

The PRESIDENT: I had the pleasure of meeting Mr. Smith, who is the President of the Royal Institute of Public Health, about three weeks ago in London, and he was very desirous that the profession should be represented at this Congress in Edinburgh.

Prof. METTAM: I beg to propose that no action be taken.

Sir JOHN M'FADYEAN: I beg to second that. I may point out, sir, that we have already come to a similar decision with regard to the invitation to attend the meeting of the Sanitary Institute.

The resolution was put and carried.

The SECRETARY read the following letter: "Mr President and gentlemen, I desire to resign my seat on the Council and trust you will kindly accept the same at your next meeting.—Yours faithfully, (Signed) J. S. LLOYD."

The Secretary also read the following letter: "Dear Sir, as it is my intention to apply for the Examinership in Veterinary Surgery and Obstetrics rendered vacant by the death of Mr. Hunting, I regret to formally place my resignation as Councilman in your hands now instead of waiting until June when my place would in the ordinary way of things have become vacant owing to the expiration of time limit. It is with great regret that I do this, as the duties of the Council have always been of a most pleasant nature.—Yours faithfully, F. HOBDAY."

Mr. PRICE: I move that those resignations be accepted.

Mr. BARRETT: I second that.

The resolution was put and carried.

The SECRETARY: I have a letter from a member of the College who wishes me to bring it before the Council, but he says that he wishes it to be strictly confidential. It is with regard to the Imperial Staff, Veterinary Department, in India. Possibly the Council might like to go into Committee to hear the letter read.

On the motion of Sir John M'Fadyean, seconded by Mr. Abson, the Council then resolved itself into Committee.

On the Council resuming its sittings in public,

Mr. TRIGGER: I move that a Committee consisting of Sir John M'Fadyean, Mr. Barrett, Mr. Mulvey, Mr. Price, and Mr. Share-Jones be formed to consider the question referred to in the letter, with authority to act, and, in the event of evidence being given, that Sir John M'Fadyean be asked to represent the Council.

Maj.-General THOMSON: I second that.

The resolution was carried unanimously.

The SECRETARY read the following letter addressed to the President, from Sir Stewart Stockman, the Hon. Sec. of the Tenth International Veterinary Congress: "I am requested by the Organising Committee of the Tenth International Veterinary Congress, which is to be held in London from the 3rd to the 8th August, 1914, to inform you that the subjects which will be discussed include (1) Questions relating to Contagious Diseases of Animals; (2) Veterinary Science in relation to Public Health; (3) Pathology and Bacteriology; (4) Epizootiology; (5) Veterinary Medicine and Surgery, and (6) Tropical Diseases. I am to invite you to honour the Congress by your presence, or to be represented by a delegate. The subscription for ordinary members is fixed at £1. I enclose herewith a form of application for membership, which should be filled up and returned as soon as possible."

Prof. METTAM: I propose that the invitation be accepted, and that the President for the time being be appointed the delegate of this Council.

Mr. MULVEY: I second that.

The resolution was carried unanimously.

FINANCE COMMITTEE.

Mr. MASON read the following report of a meeting of the Finance Committee, held on Friday, 3rd April:—

Chairman: The Secretary reported that a letter had been received from Mr. A. Lawson, Chairman, stating that he was unable to attend owing to illness.

It was resolved—That Mr. A. W. Mason be appointed to the Chair, and, that a letter be forwarded to Mr. Lawson expressing the regret of the Committee at his illness, and the hope that he would soon be recovered.

Financial Statement: The Treasurer submitted his financial statement for the quarter, showing an adverse balance of £46 10s. 10d., and liabilities amounting to £149 0s. 8d.

It was resolved—That the financial statement be approved, and that the Treasurer be ordered to pay the liabilities shown, together with cheques for monthly salaries, petty cash, insurance, Fellowship examiners' fees, gas, and electric light. That the Treasurer be empowered to sell out £1000 Consols if found necessary.

International Veterinary Congress. The question of the forthcoming International Veterinary Congress, referred to this Committee by the Parliamentary Committee, was considered, but the Committee decided to make no recommendation.

Register, 1913. The Secretary submitted the publishing account in connection with the Register, 1913, which was considered to be very satisfactory.

Sir JOHN M'FADYEAN: Might I ask the Chairman of the Committee whether the question considered in relation to the International Veterinary Congress was the propriety of this Council making a donation to the expenses?

Mr. MASON: Yes. It was thoroughly discussed, and the Committee decided to make no recommendation.

Sir JOHN M'FADYEAN: I can only say that I think when the list of donations comes to be scrutinised hereafter it will strike impartial observers as very remarkable that outside bodies, such as the Royal Agricultural Society of England, the Highland and Agricultural Society of Scotland, and various Councils of the Breed Societies have given substantial donations to this purely Veterinary Congress, and that this body has not given anything, but I make no counter proposition, sir.

Mr. MULVEY: I presume all those bodies are in a fairly good financial position, and are not, as this College is just now, in an impecunious position.

Sir JOHN M'FADYEAN: That is the reason, may I suggest, that it ought to have been embodied in the report of the Committee meeting.

Prof. METTAM: I should just like to say that the question was only brought up in an informal fashion. The Committee had no application from this Congress before it. It was merely a general talk round the table, and the Committee decided to make no recommendation because nothing had been put before us.

Sir STEWART STOCKMAN: I would like to say that I think that ought to appear on the minutes as an explanation, because it says the question was considered.

Mr. TRIGGER: The Committee thoroughly threshed it out, and thought this was the more dignified attitude to adopt.

Mr. MASON: I should like to say, as Chairman, in answer to the several questions or insinuations that have been thrown out, that the reason no recommendation was made was that the College is not in a position to give a sum of money to a certain fund for entertainments. The word used was "Entertainments." We are not in a position to give an entertainment. I also should like to say, on behalf of the Chair in defence of the Committee's action, that we have had no application asking us for anything yet.

Mr. TRIGGER: There was another matter mentioned at the meeting of the Committee which it was thought

should be brought before the Council so that it could be brought to the notice of the profession, and that was in regard to the Registrar. We thought the excellent results that our Registrar has been able to produce, in the shape of converting what used to be a very heavy yearly debit into a small profit, or really a reasonable profit, should be called attention to—(hear, hear)—as it is very much to the credit of the Registrar. I think the Council might have the figures before them, if you would kindly read them out.

The PRESIDENT: The Secretary will read the figures out.

The SECRETARY: The publishing account for the Register for 1913 shows receipts from advertisements £24 10s.; from sales £47 12s. 2d., making total receipts of £72 2s. 2d. The expenditure on printing and binding was £60, and on postages £4 9s. 0½d., the balance, profit on the year, being £7 13s. 1½d. In addition 167 free copies were issued to new graduates, to members of Council, to public libraries and other institutions.—(Cheers.)

The PRESIDENT: I think that is very satisfactory, gentlemen. (Hear, hear.)

On the motion of Mr. Abson, seconded by Mr. Trigger, the report of the Finance Committee was then unanimously adopted.

PRELIMINARY EXAMINATION COMMITTEE.

Mr. MULVEY read the following report of a meeting of the Preliminary Examination Committee held on Thursday, April 2nd:

Present: Mr. W. J. Mulvey in the Chair, Dr. Bradley, Mr. Carter, Sir John M'Fadyean, Prof. Mettam, and Mr. Share-Jones.

Preliminary Educational Examinations. It was resolved—

(a) *List of Examinations.* That, in addition to the examinations included in the present Schedule I, the following examinations recognised by the General Medical Council be approved:—

Final Examination for a Degree in Medicine of any University in the United Kingdom.

Oxford and Cambridge Schools' Examination Board: The School (or Leaving) Certificate Examination.

University of Durham: Matriculation Examination of the Faculties of Medicine, Science, Letters and Music.

University of Birmingham: Senior School Leaving Certificate.

University of Dublin: (1) Junior Freshman Term Examination (exclusive of Trigonometry).

(2) Special Preliminary Examination to be held in March, the standard and subjects of which shall be those of a Junior Freshman Examination (exclusive of Trigonometry).

(3) Junior Exhibition Examination on obtaining marks of sufficient merit in the subjects of (a) or (b).

University of Calcutta: Matriculation Examination, Intermediate or Final Examination for Bachelor's Degree in Arts or Science.

University of Madras: Intermediate Examination.

University of Allahabad: Matriculation Examination.

University of Manitoba: Matriculation Examination.

University of Hong Kong: Matriculation Examination in Medicine.

(b) That the following Educational Examinations be approved:—

College of Preceptors: Preliminary Examination in General Education. (The required subjects to be passed at one time).

Educational Institute of Scotland: Preliminary Examination in General Education. (The required subjects to be passed at one time).

Carried with one dissenter.

(c) That, with the exception of the examinations mentioned in paragraph (b), the required subjects must be passed at not more than two examinations.

(d) *Required subjects.* That the required subjects be as follows:

1. English (grammar, paraphrasing, composition, questions on British history and geography).

2. Mathematics (arithmetic, algebra, including easy quadratic equations; geometry, including the subject matter of Euclid, Books I., II., III., and simple deductions).

3 and 4. Two of the following subjects: Latin, Greek, French, German, or any other modern language, (Grammar, translation into English from unprescribed books; translation from English).

(e) That Schedule I, as revised in accordance with the above recommendations, be suspended at once for approval by the Council in due course.

Bristol University Schools' Examination. An application was received from the Bristol University for the recognition of the schools' examination, and it was resolved—That the examination be not recognised until it has been approved by the General Medical Council.

Mr. MULVEY: I move the reception of the report, sir, and in doing so I desire to say that I do not agree with all the recommendations made by the Committee. You will notice, sir, that there were present at the meeting yesterday four representatives of schools and two laymen, one of whom, myself, occupied the Chair, and therefore did not vote. I should like to mention also that in taking the vote there were two gentlemen who approved of all these recommendations; there were two others who signified their acquiescence by their silence, and another one, Mr. Share-Jones, who entered an objection. I, myself, being in the Chair, did not vote. Sir, I deprecate very much any retrograde movement in the way of education connected with this body. (Hear, hear.) You will notice that we are proposing a different examination altogether from what we have hitherto held. You will notice that at the present time it is stated under Clause 3 on page 83:—"College of Preceptors: Examinations for first-class certificate (the required subjects to be passed at once, or not more than two examinations). Preliminary examination for medical students (the required subjects to be passed at one time). Educational Institute of Scotland: Preliminary medical examination (the required subjects to be passed at one time). Royal College of Physicians and Surgeons in Ireland: Preliminary examination (the required subjects to be passed at one time)." It is proposed by this Committee to substitute for that an examination by the College of Preceptors, which is styled a "preliminary examination in general education," and in the Educational Institute of Scotland a "preliminary examination in general education." It goes on to define what that examination shall consist of, but nothing is said as to how these subjects are marked. These subjects can be taken at any continuation Board School, and are examined on daily in London at all events. So that it seems to me that you are really lowering the tone of your entrance examination.

Sir JOHN M'FADYEAN: That is an absolute misrepresentation of the intention, and in reality of the effect, of the recommendation of the Committee.

Mr. GARNETT: I rise to a point of order, sir. The point which we have to consider just now is the Report of the Preliminary Examination Committee. What we are listening to at the present moment is a second reading speech.

Sir JOHN M'FADYEAN: The report has not been received yet.

Mr. MULVEY: I am moving the reception of the report, and on the motion for the reception of the report I am entitled, according to all the laws of debate, to say something on the question.

The PRESIDENT: Let us get it received first, and then we can discuss it afterwards.

Mr. MULVEY: I have finished; I have said all I want to say.

Sir JOHN M'FADYEAN: To put the thing in proper order, I will second the motion that the report be received.

Sir STEWART STOCKMAN: Do I understand that Mr. Mulvey's motion is that the report be received or not received? I am under the impression that he was moving that it be not received.

Mr. MULVEY: I have moved nothing except that it be received.

Sir JOHN M'FADYEAN: I second that.

Mr. MULVEY: Not adopted.

The PRESIDENT: It is moved and seconded that the report of the Preliminary Examination Committee be received.

The resolution was put and carried.

Sir JOHN M'FADYEAN: Sir, as the Chairman of the Committee has definitely stated that he will not move the adoption of the report, I will take that duty on myself; and I take the opportunity to say that in my opinion the Chairman of the Committee has absolutely misinformed the Council, no doubt quite intentionally—(Much laughter)—I meant quite unintentionally—(Laughter)—that was too obvious a slip—as to the intentions of the Committee, and the effect of recommendations which they have made. It will be in your recollection that Mr. Mulvey said, or indicated, that we were recommending a step which would have to be considered as retrograde. I should like to tell the Council what the intention of the majority of the Committee was, and you will judge from that whether our intentions were retrograde or not. Our intentions were to leave the standard of the Preliminary Examination in the meantime absolutely where it has been. We suggest no alteration, except that the Educational Institute of Scotland and the College of Preceptors should be authorised to conduct a special examination for intending veterinary students on the same standard as the examination which they have been conducting during recent years. I challenge Mr. Mulvey to deny the accuracy of that, and I further challenge him to deny that that will be the effect, and the sole effect, of these recommendations, if the bye-laws are altered in accordance with the recommendations. I do not think it would be desirable to have a long discussion on this question at the present time, because the recommendations cannot be put in force until they are passed by the Council after due notice, and any discussion that we have now would inevitably have to be repeated next July. If, however, it is decided that it is desirable that we should discuss now whether we should raise the standard of the Preliminary Examination or leave it where it is, I reserve to myself the right to join in the discussion. Meanwhile, I move that the report be adopted.

Mr. SHARE-JONES: I have an addendum to move to the report; it is not an amendment. Sir John knows exactly the resolution which is in my mind. I am prepared to vote for the report as it stands at present if you will permit me to move afterwards the addition to the resolution which I moved in Committee yesterday, so that it may be put to the vote of the Council. (Several members: What is it?) It is an addendum. It is not an amendment.

Mr. MASON: Read it.

Sir JOHN M'FADYEAN: It is with regard to the science subjects, is it not?

Mr. SHARE-JONES: No, with regard to the date upon which the higher standard certificate may be accepted.

Sir JOHN M'FADYEAN: That is not directly an amendment to the report.

Mr. BARRETT : Read it.

Mr. SHARE-JONES : The addendum is this : "That on and after December 31st, 1915, the standard demanded in the subjects of the Preliminary Certificate presented shall be that now required by the General Medical Council."

Mr. SUMNER : That has been passed already.

Sir JOHN M'FADYEAN : The majority who are on the Committee cannot accept that. It seems to me the proper way to test the feeling of the Council with regard to that, is to give notice of your intention to have the bye-laws altered in accordance with that resolution.

Mr. SHARE-JONES : If we are to stick to red tape, Sir, I should like to draw your attention to the resolution of the Council last July which states specifically that the principle of raising the standard of our Preliminary Examination has been approved by this Council. We do not raise it on a quibble ; we allowed it to go back last time. It had been previously approved on the unanimous vote of the Council. I am sorry, Sir John, but after that resolution, which is on the Minutes, I certainly should like, and I think the Councillors present to-day would like, to have an opportunity of voting again on that principle.

Sir JOHN M'FADYEAN : You will have the opportunity.

Mr. SHARE-JONES : If you allow me to move that to test the feeling of the Council, I will vote for the report as it stands at present—if you will allow me to move that addendum afterwards as a resolution.

A MEMBER : We cannot stop you.

Sir JOHN M'FADYEAN : Mr. Share-Jones is quite out of order, if he will allow me to say so, in making these offers to me ; I have nothing to do with what the Council will decide on these matters when they come up. I do not care whether the report of the Committee is adopted or not ; it is my intention formally to give notice that the bye-laws be altered in accordance with these recommendations, and the matter will come up for discussion at the next quarterly meeting.

Mr. SHARE-JONES : I move now that there be added to the Report : "That on and after December 31st, 1915, the standard demanded in the subjects of the preliminary certificate presented shall be that now required by the General Medical Council."

The PRESIDENT : At the present time ?

Mr. SHARE-JONES : Now.

Sir JOHN M'FADYEAN : On a point of order, Sir, I submit that it is absolutely improper for Mr. Share-Jones without previous notice to ask the Council to vote on that subject, because it involves an alteration of bye-laws—(hear, hear)—and if it is allowed Mr. Jones will be no further forward than he is now.

Mr. SHARE-JONES : I am very sorry, but I must remind the members of the Council of what occurred yesterday. I was told distinctly yesterday that I might bring this matter up, and that the proper thing for me to do was to bring this matter before open Council to-day. Practically the same thing was told to the Chairman of the Committee ; he was told yesterday that it would be a proper opportunity, and a fine opportunity, for him to make a speech on the question here to-day ; and yet when we come and take the steps which we were practically recommended to take we are met with these objections.

Sir JOHN M'FADYEAN : I really cannot allow that to pass. What I said was that you would have the right to make a speech before the Council touching the question of the acceptance of the report. I never suggested that you would be in order in moving formally an alteration of the bye-laws.

Mr. TRIGGER : I rise to a point of order.

Mr. SHARE-JONES : I have the promise of the President to move this after the adoption of the report.

Mr. BARRETT : On a point of order, Sir, there seems to be some conflict between the two schools of thought as to this preliminary examination. Personally, I have not considered the matter, nor have I made up my mind, but I submit Mr. Share-Jones is perfectly in order in moving any amendment or any addendum to this Report.

The PRESIDENT : After it has been adopted.

Mr. BARRETT : No, before.

The PRESIDENT : Not according to the Solicitor's ruling.

Mr. BARRETT : Does Mr. Thatcher say so ?

The PRESIDENT : Yes. It can be moved after the adoption. The adoption of the report of the Preliminary Examination Committee has been moved and seconded. I will now put the motion.

Sir JOHN M'FADYEAN : Do I understand that Mr. Barrett wanted to give some reasons against the adoption of the report, because if so, surely he should give them now.

Mr. BARRETT : No, not against the adoption of the report, but I submit, with due deference to Mr. Thatcher's advice, that Mr. Share-Jones is perfectly entitled to move any amendment that he pleases.

The PRESIDENT : Afterwards.

Mr. BARRETT : And that it will be preferable to vote on the suggestion before the report is adopted. We have done that over and over again in regard to the reports of other committees.

The PRESIDENT : I am simply going on the ruling of the solicitor.

Mr. BARRETT : If Mr. Thatcher says the other way I will sit down.

Mr. THATCHER : The proper course, it seems to me, is this, that the motion for the adoption of the report will now be put. If it is adopted, well and good ; then Mr. Share-Jones has a right to move a resolution on the subject.

Mr. SUMNER : After its adoption ?

Mr. THATCHER : Yes. But after all his resolution might refer to an alteration of bye-laws, so that at present it is a mere pious opinion.

Mr. SHARE-JONES : I would like to remind the Council—I do not want to waste the Council's time more than anybody else does—that that was precisely the question I put when I stood on my feet at first, as to whether I should be entitled to move that now or after the report had been adopted. With the promise that I shall move this after the report has been adopted, I am prepared to vote for the report as it stands.

The motion for the adoption of the report was then put and carried. Mr. Mulvey voting against.

Mr. SHARE-JONES : Now I move this resolution : "That on and after December 31st, 1915, the standard demanded in the subjects of the preliminary certificate presented shall be that now required by the General Medical Council."

Sir JOHN M'FADYEAN : I rise to a point of order. I desire, sir, that you should take the opinion of the Solicitor whether this is in order. This is a proposal that we should alter the Bye-laws, and I hold that to be improper unless due notice has been given to the Council. (Hear, hear.)

Mr. SHARE-JONES : With all due respect to you, Sir John, I had the promise of the Chair that I could move this. You all heard it read. I was asked to read it, and it was read. The substance of the resolution was known to every member of the Council, and I asked for the promise of the Chair that I should be allowed to move it before I voted for the report.

Mr. SUMNER : That is so.

Mr. SHARE-JONES : I got the promise of the President before I voted on the report. If you are going back on an honourable understanding with the Chair, then I must ask you to go back upon your vote.

Mr. GARNETT: It is well known to all members of this Council that there can be no alteration of Bye-laws unless notice has been properly given and suspended. If we were to pass Mr. Share-Jones's resolution it would have no effect whatever, it would all have to come up again. He must, if it involves the alteration of Bye-laws, give notice, and suspend the notice for at least three months.

The PRESIDENT: That is so.

Mr. SHARE-JONES: May I ask if the necessary notice has been given of these alterations which were made yesterday, and which have been voted upon to-day?

Sir JOHN M'FADYEAN: No.

Prof. METTAM: Notice of the alterations will have to be suspended, and they will have to come up for discussion again.

Mr. BARRETT: On a point of order, sir, Mr. Garnett is no doubt perfectly right, that if an opinion were expressed now which is contrary to the present Bye-laws it would have no effect, but surely Mr. Share-Jones, after the understanding he had with you, sir, and with honourable members, is entitled to say "I desire the opinion of the Council upon this point, whatever it may be worth."

Sir JOHN M'FADYEAN: I submit that is not what Mr. Share-Jones has done. Mr. Barrett has no right to alter the words which Mr. Share-Jones has used. He has moved an alteration of the Bye-laws. Really I appeal to the Council not to waste time. None of us wish to burke discussion on this point, but I submit to Mr. Share-Jones that, inasmuch as the recommendations in the report of this Committee are absolutely ineffectual until formal notice has been given and they have been passed by the Council, he will sacrifice nothing by waiting till next July to move what it is now his intention to move.

Mr. SHARE-JONES: I give notice now that I will move this alteration. (Hear, hear, and a voice "That is right.")

Sir JOHN M'FADYEAN: That is No. 10 on the agenda.

Mr. SHARE-JONES: It is pure twisting. I surely had the permission of the Chair.

Mr. BARRETT: I do not agree with Sir John at all. I think Mr. Share-Jones, especially after what was said to him, is perfectly right, irrespective of the nature of the resolution, to take the present opinion of this Council upon this specific point, if he desires to do so. It has no relation to giving notice of motion at all. He is entitled to take the opinion of the Council upon this particular point for what it is worth. (Cries of "Next business.")

Mr. SUMNER: Mr. Share-Jones had a promise which has not been fulfilled.

The PRESIDENT: I gave Mr. Share-Jones consent to express his opinion before this Council, and he has done so.

Mr. SHARE-JONES: You did not. (Hear, hear, and cries of "Chair, Chair.") I desire to do it now, and Sir John got up, and I was ruled out of order.

The PRESIDENT: You can give notice of motion.

Mr. SHARE-JONES: I wish to give notice of motion.

The PRESIDENT: That comes under No. 10 on the agenda.

Sir STEWART STOCKMAN: If that was all Mr. Share-Jones wished to be allowed to say, I have heard it myself three times. I am quite satisfied I know what your motion is.

Mr. SHARE-JONES: But I have something to say on it, and that something has rather an important bearing on the attitude which some men take from one quarter and another towards matters which are vital to this Council and to the profession. That something can be equally as well said three months hence as to-day, and it will be said then. (Hear, hear.) You accept that notice of motion, sir?

The PRESIDENT: No. That will come on under No. 10.

Mr. SHARE-JONES: I may not be here then.

The PRESIDENT: You can get somebody else to give notice in your absence.

EXAMINATION COMMITTEE.

Mr. MULVEY read the following report of a meeting of the Examination Committee held on Thursday, April 2nd.

Educational Certificates. (a) Educational certificates numbered 1419 to 1434 inclusive were submitted and approved.

(b) An educational certificate submitted from Mr. R. F. J. Hayward was considered. This did not comply with the Bye-laws, and was not accepted.

Exemption. An application was received from Mr. D. H. Cox, B.A., for exemption from the first year's course of study, under Bye-law 62 (a), in virtue of his holding the Diploma of Bachelor of Arts of the University of Cambridge, in the subjects of Chemistry, Botany, and Physiology.

It was resolved that the application be granted.

Exempted Students: Special examination in Anatomy It was resolved:

(a) That candidates examined under the provisions of Bye-law 62 (a) shall, in addition to the usual examination in Anatomy, be examined orally for fifteen minutes in the subject of Anatomy; Bones, Ligaments, and Joints.

(b) That the fee for the special examination in Class B be fixed at £8, and in case of rejection in Class B the re-examination fee be fixed at £4 4s.

(c) That for each candidate examined under these regulations the Examiners in Anatomy, Class B, shall receive a fee of 10.6.

(d) That the alterations to bye-laws necessitated by these resolutions be suspended at once for approval by the Council in due course.

Williams Memorial Prize. A letter was received from the winner of the Williams Memorial Prize, 1913, with regard to the nature of the prize, and it was resolved—"That in future the Williams Memorial Prize be awarded in money."

On the motion of Mr. Mulvey, seconded by Mr. Mason, the report was received and adopted.

REGISTRATION COMMITTEE.

The SECRETARY read the report of a meeting of the Registration Committee held on Thursday, April 2nd, from which it appeared that 16 cases were considered by the Committee.

In the case of G. R. Leighton, the Solicitor reported the correspondence he had had with the Local Government Board for Scotland, and it was resolved that the matter be left to the President to arrange for the question to be raised in Parliament at an opportune moment.

A member appeared before the Committee, accompanied by his solicitor, to answer a charge of employing an unqualified assistant in such a way as to contravene Bye-law 54.

The offence was that on June 6th, 1913, this member had permitted his unqualified assistant to examine a horse under the Importation of Horses, Asses, and Mules (Ireland) Order, 1907, and to sign the certificate in the name of the member.

In answer to the charge the member's solicitor admitted the offence, but urged that it was committed in ignorance, and without intent to commit a breach of the Bye-laws.

It was resolved that this Committee find that the acknowledged relationship between this member and his unqualified assistant amounts to covering, which is conduct disgraceful in a professional respect, that he be

severely censured, but that the final report of the Committee to the Council be deferred for six months.

The member on being readmitted was informed of the decision of the Committee, and gave an undertaking that the offence should not occur again.

Five cases were ordered to be struck out in the absence of proper evidence, and the Solicitor or Secretary were instructed with regard to the proceedings to be taken in the other cases.

Correspondence. (a) A pamphlet of testimonials by veterinary surgeons in favour of Petroleum Jelly was submitted, and the Secretary was instructed to communicate with the members in question, calling their attention to Bye-law 55 and requesting an explanation.

(b) A letter was received from Mr. H. O. Oliver, of Sydney, Australia, who passed his Final Examination in 1898, but who had not signed the Register of Members.

The Secretary reported that he had informed Mr. Oliver that he must comply with Bye-law 93 before his name could be entered in the Register of Veterinary Surgeons. The matter was left in the hands of the Secretary to report, if necessary, to the next meeting of the Committee.

Other correspondence was submitted, and the Secretary was instructed as to the replies to be sent.

Application for Restoration. The application received from Mr. George Campbell Hill, whose name was removed from the Register in 1908 under Section 6 of the Veterinary Surgeons Act, considered at the previous meeting of Committee, was again submitted. Further testimonials were received from members of the College practising in Glasgow.

It was resolved to recommend—That the name of Mr. George Campbell Hill be restored to the Register of Veterinary Surgeons.

Professional Etiquette. It was resolved—That the Bye-laws with regard to professional etiquette be referred to the Bye-laws Sub-Committee for revision and report.

On the motion of the President, seconded by Mr. Trigger, the report was adopted.

PARLIAMENTARY AND GENERAL PURPOSES COMMITTEE.

Mr. GARNETT read the following report of a meeting of the Parliamentary and General Purposes Committee held on Thursday, April 2nd.

Parliamentary Bills. The following Parliamentary Bills were submitted:—Dogs; Higher Animals Protection; Docking of Horses; Animals (Anæsthetics); Exportation of Horses.

(a) With regard to the Dogs, Higher Animals Protection, and Animals (Anæsthetics) Bills, it was reported that these Bills would be blocked.

(b) It was resolved that no action be taken with regard to the Docking of Horses Bill.

(c) *Exportation of Horses.* It was resolved that in the event of this Bill going to Grand Committee, the Chairman be requested to obtain permission to attend to give evidence on behalf of the College.

Supplementary Charter. The Solicitor reported that the petition for the Supplementary Charter had been presented, and that no protest against it had been received. The matter would now take its usual course.

International Veterinary Congress. The question of the action to be taken by the College in connection with the forthcoming International Veterinary Congress was considered, and referred to the Finance Committee.

Cleaning of Building. This question was ordered to stand over.

On the motion of Mr. Garnett, seconded by Mr. Mason, the report was received and adopted.

ANNUAL FEE COMMITTEE.

Sir JOHN M'FADYEAN read the following report of a meeting of the Annual Fee Committee held on Thursday, April 2nd.

Veterinary Surgeons Act Amendment Bill. The Solicitor reported that the Veterinary Surgeons Act Amendment Bill had been presented in the House of Commons on the 18th February, but that no further progress had been made.

It was resolved to recommend—That, in view of the impossibility of further progress being made this session, no further expense be incurred in connection with the Bill during the present session of Parliament.

On the motion of Sir John M'Fadyean, seconded by Mr. Abson, the report was adopted.

HONORARY ASSOCIATES COMMITTEE.

Prof. METTAM read the following report of a meeting of the Honorary Associates Committee held on Thursday, April 2nd.

Nominations. Nominations were submitted and considered.

It was resolved—That the consideration of the matter be deferred *sine die*.

Prof. METTAM: I move the reception and adoption of the report.

Mr. PACKMAN: I second that.

Mr. BARRETT: At the last meeting of Council Prof. Hobday desired that a certain name should be added to the list that was presented, and I think Prof. Mettam said the Committee would consider the question. Has that been done, and has anything been decided?

Prof. METTAM: Yes, it was considered yesterday.

Mr. BARRETT: May I ask with what result.

Prof. METTAM: Yes; it is in the last line of the report: "That the consideration of the matter be deferred *sine die*."

Mr. BARRETT: Thank you very much.

The motion for the adoption of the report was then put and carried unanimously.

LIBRARY AND MUSEUM COMMITTEE.

Dr. BRADLEY read the following report of a meeting of the Library and Museum Committee held on Friday, April 3rd:

Presentations. The Secretary reported that since the date of the previous quarterly meeting of Council the following presentations had been made to the Library, and it was resolved, that a vote of thanks be conveyed to the respective donors:—

The Calendar of the Pharmaceutical Society of Great Britain, 1914; The Registers of Pharmaceutical Chemists, and Chemists and Druggists, 1914; Calendar of the Pharmaceutical Society of Ireland, 1914; Calendar of the University of Liverpool, 1914; Memoirs of the Department of Agriculture in India, Vol. 1, No. 4; Annual Report by the Chief Veterinary Officer of the Board of Agriculture and Fisheries for the year 1912; Municipal Council of Johannesburg: Report of Director of Abattoir and Live Stock Market, 1912-1913; Annual Report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, 1912-1913; A Note on the M'Fadyean Staining Reaction for Anthrax Bacilli, by Major J. D. E. Holmes (Bulletin No. 36); The Diagnosis of Dourine by Complement Fixation, by John R. Mohler; Annalidella Stazione Sperimentale per le malattie infettive del bestiame, Vol. 1, 1911-1913; The Rhodesian Agricultural Journal, December 1913, February, 1914; Revue de Pathologie Comparée, December 1913, January and February 1914; The Journal of the Board of Agriculture, January (with supplement), February and March 1914; Orders of the

Board of Agriculture and Fisheries; Leaflets of the Board of Agriculture and Fisheries; *The Veterinary Journal*, *The Veterinary News*, and *The Veterinary Record* for the quarter; *The World's Carriers* for the quarter; Annual Report of Proceedings under the Diseases of Animals Acts, The Market and Fairs (Weighing of Cattle) Acts, etc., for the year 1913; *The Bloodstock Breeders' Review*, April 1914.

Purchases. The Secretary reported that the following books had been purchased for the Library:—

Tropical Diseases Bulletin, Vol. 3, Nos. 1, 2, 3, 4, 5, and 6; Tropical Veterinary Bulletin, Vol. 2, No. 1; Report of the Departmental Committee appointed by the Board of Agriculture and Fisheries to inquire into Epizootic Abortion, Parts, 1, 2, and 3; appendix to Part 3.

Completion of Sets. The Secretary called attention to the fact that several sets of foreign periodicals were incomplete, and suggested that he should be allowed to insert a notice in the British veterinary journals asking for gifts of volumes to complete the series in the Library.

It was resolved that the matter be left in the hands of the Secretary.

On the motion of Dr. Bradley, seconded by Prof. Mettam, the report was received and adopted.

ELECTION OF EXAMINERS.

On the motion of the President, seconded by Mr. Clarkson, the Council went into Committee in order that the applications and testimonials received in connection with the election of examiners might be read.

On the Council resuming its sittings in public, a ballot was taken for the election of an Examiner in Class D. Veterinary Surgery and Obstetrics, the following gentlemen having made applications for the appointment:—Messrs. John Brown, F.R.C.V.S., F.T.G. Hobday, F.R.C.V.S., F.R.S.E., John Penberthy, F.R.C.V.S., (nominated by Mr. Mulvey); Graham Rees-Mogg, F.R.C.V.S., (nominated by Major-General Pringle).

The ballot resulted as follows: Hobday 9, Penberthy 7, Rees-Mogg 6, Brown 1.

The PRESIDENT: As it is necessary to have an absolute majority of those voting, we must have another ballot among Mr. Hobday, Prof. Penberthy, and Mr. Rees-Mogg.

Mr. CLARKSON: I should like a ruling on that point, sir, as to whether we take a ballot between the top two or the top three.

Sir JOHN M'FADYEAN: The second ballot will be between Mr. Hobday and Prof. Penberthy, will it not?

Mr. SUMNER: The Solicitor says that we must vote on the three.

Mr. GARNETT: You rule on the three, do you?

Mr. THATCHER: Yes, I think so. There is no absolute majority.

The PRESIDENT: Gentlemen, you must now vote on the three names: Hobday, Penberthy, and Rees-Mogg.

Mr. THATCHER: I really think this is absurd. There is only one vote that can be given to the other candidates this time—the vote that was given to Mr. Brown before. With great respect, I say it is ridiculous. I think we ought only to vote for two this time. If we vote for three we shall all vote again as we did last time, and there is only one vote, that given to Mr. Brown, that can be given to the other candidates.

Mr. SUMNER: They may not vote the same this time.

Mr. THATCHER: We must have an absolute majority.

Mr. SUMNER: What is an absolute majority?

The PRESIDENT: The Solicitor says we must ballot again among the first three.

A second ballot was then taken, and resulted as follows:—Penberthy 9, Hobday 8, Rees-Mogg 6.

The PRESIDENT: We must have another ballot, as Prof. Penberthy has not an absolute majority.

Mr. THATCHER: Had you not better move a resolution that the candidate who receives the largest number of votes is elected?

Mr. ABSON: Not this time, next time.

A third ballot was then taken between Prof. Penberthy and Mr. Hobday, and resulted as follows: Hobday 13, Penberthy 10.

The PRESIDENT: I declare Mr. Hobday elected the Examiner in Class D., Veterinary Surgery and Obstetrics.

ELECTION OF EXAMINER IN VETERINARY HYGIENE AND SANITARY SCIENCE FOR THE FELLOWSHIP DEGREE.

The Council then proceeded to the election of an Examiner in Veterinary Hygiene and Sanitary Science for the Fellowship Degree, for which the following gentlemen had made applications: Messrs. A. C. Duncan, F.R.C.V.S., J. S. Lloyd, F.R.C.V.S., D.V.S.M., W. Woods, F.R.C.V.S., (nominated by Mr. W. J. Mulvey).

The PRESIDENT: Will somebody move now that the candidate who receives the highest number of votes be elected?

Mr. PRICE: I move that.

Sir JOHN FADYEAN: You cannot do it.

The PRESIDENT: I consulted the Solicitor before saying that.

Mr. THATCHER: I think it can be done by resolution.

Prof. METTAM: Then it should have been done before the first ballot was taken in the first case.

Prof. BRADLEY: I move as an amendment that we vote as we did before.

The PRESIDENT: Very well, I only suggested it with the object of saving time.

A ballot was then taken, and resulted as follows:—Woods 20, Lloyd 1, Duncan 1.

The PRESIDENT: I declare Mr. Woods elected Examiner in Veterinary Hygiene and Sanitary Science for the Fellowship Degree.

REPORT ON FELLOWSHIP EXAMINATION.

The SECRETARY: I have to report that since the previous quarterly meeting of Council the following gentlemen have been admitted Fellows by examination: Messrs. Richard Finch, S. J. Motton, W. T. Brookes, G. B. C. Rees-Mogg (Capt.), Charles Hartley, Jun.

APPOINTMENT OF SCRUTINEERS.

Mr. MASON: I move that the same gentlemen as last year be asked if they will kindly attend this year, and that the President be empowered to fill any vacancies.

Mr. PRICE: I second that.

Mr. BARRETT: Was there any difficulty in getting scrutineers last year?

The SECRETARY: No, sir.

The resolution was put and carried unanimously.

ANNUAL DINNER.

The PRESIDENT: The next question is to decide as to whether we are to hold an annual dinner.

Mr. TRIGGER? I move that no action be taken.

Maj.-General THOMSON: I second that.

The resolution was put and carried unanimously.

NOTICES OF MOTION.

Mr. BARRETT: I have been asked by Mr. Share-Jones to give notice of the following motion. I do not say I agree with it. I simply give notice on his behalf:—“That on and after December 31st, 1915, the standard demanded in the subjects of the Preliminary Certificate presented shall be that now required by the General Medical Council.”

Mr. GARNETT: May I ask which bye-law that amends?

Mr. BARRETT: I do not know. I have not looked up the subject.

Sir JOHN M'FADYEAN: I beg to give notice of my intention to move certain alterations in connection with the first schedule. The alterations are perhaps too long for me to read out to the Council, but they are those made in the report of the Preliminary Examination Committee which was adopted at an earlier part of these proceedings. Of course the notice of the alterations will be suspended on the board.

Mr. MULVEY: I beg to give notice of the following alterations: "Bye-law 67: An examination fee of £5 shall be paid for each examination. In the case of candidates claiming exemption from the examination in Class A under Bye-law 62 (a) a fee of £8 shall be paid by each such candidate on presenting himself for the first time for the Class B examination.

Bye-law 68: Should a student fail in any examination he shall pay a further fee of £3 3s. for each re-examination. In the case of candidates examined in Class B under the provisions of Bye-law 62 (a) a sum of £4 4s. shall be paid for each re-examination in Class B.

Bye-law 94: Every successful candidate in the final examination shall be required to pay a fee of £1 for registration as a member of the College, and to subscribe his name to the rules and bye-laws of the College for the time being."

On the motion of Mr. Abson, seconded by Mr. Clarkson, a hearty vote of thanks was accorded to the President for his conduct in the chair, and the meeting terminated.

Personal.

On the recommendation of the Public Health Committee of the London County Council it has been resolved that Mr. D. H. WOOD, M.R.C.V.S., be appointed a permanent veterinary inspector under the Dairies, Cowsheds, and Milkshops Order of 1899, and the L.C.C. (General Powers) Acts, 1904 and 1907, and the Tuberculosis Order of 1913. The salary to be £350 per annum, rising by annual increments of £25 to a maximum salary of £400 per annum.

Mr. J. C. COLEMAN, M.R.C.V.S., has been appointed veterinary inspector to the Swindon Town Council under the Diseases of Animals Acts for the 12 months commencing April 1, 1914.

Mr. A. D. MINOR, M.R.C.V.S., Chief Veterinary Inspector, has been granted an increase of salary from £350 to £400 per annum by the Manchester City Council.

A TREATMENT FOR CHOKING.

Sir,

The enclosed cutting of evidence produced in court of a novel treatment for choking, used by a farmer on the Fraser River, may be of interest to your readers. It is certainly the most ludicrous I ever heard of.—Yours truly,

T. R. R. HOGGAN, M.R.C.V.S.

Vancouver, B.C. March 16.

"On one occasion a cow on Mr. La Fond's farm was choking over a potato. Mr. La Fond placed an axe on one side of the animal's throat and forced the potato up against the skin of the opposite side. Seizing a hammer Mr. La Fond then pounded the potato up into bits, but the cow still choking, Mr. La Fond then seized an old rusty crowbar and rammed it down the animal's throat as far as it would go, releasing the mashed potato."

VOL. XXVI.

PROFESSIONAL CONDUCT—OUR BYE-LAWS.

A minor but not unimportant decision reached at the last Council meeting was the resolution—"That the bye-laws with regard to professional etiquette be referred to the Bye-laws Sub-Committee for revision and report."

Presumably the mild word "etiquette" may be taken as embracing the whole subject of professional conduct, including grave forms of misconduct. Our present bye-laws upon professional conduct certainly need revision; and so, too, do those upon the somewhat allied subject of registration.

Probably there are members who would like the bye-laws to give more definite information than they now do as to what constitutes professional misconduct.

At present only two offences—advertising and covering—are directly specified as professional misconduct. Others might well be added; but we need not expect the revised bye-laws to enumerate a long list of professional offences.

It is obviously impossible to indicate all possible actions that would come under the term of "conduct disgraceful in a professional respect," and this explains why so little has been done in defining misconduct. Still, hypothetical offences which might occur at some time are not quite on a par with other offences which we know do occur with more or less frequency. We know, for instance, that a few veterinary surgeons "solicit." "Soliciting" is universally recognised as unprofessional conduct, and men have been struck off the Register for indulging in it. That, and a few other actions of similar frequency and gravity, might advantageously be declared unprofessional by bye-law.

We hope that the bye-law allowing a defendant before the Registration Committee to claim an open trial if he chooses, will be retained unaltered. In its present form it may sometimes do good, and cannot do harm. But something ought surely to be done with that peculiar bye-law which directs that whenever a member is struck off the Register after entering a defence, the R.C.V.S. shall publish a full report of both charge and defence in the professional journals not more than three or less than two months later. The bye-law is "peculiar" for this reason. Its terms are peremptory, not permissive—the word used is "shall," not "may"—but though it was passed many years ago, we are not aware that it has even once been obeyed. Much may be said against this bye-law—against the washing of dirty linen and gibbeting of ruined men that its observance entails. It might be abolished altogether, or given a more optional wording—for we can imagine cases in which publication might be desirable, but to retain it unaltered as a dead letter is indefensible.

SUNSTROKE IN A THOROUGHbred AMERICAN GELDING.

Brown gelding Balbek, 9 years old, property of the Georgetown Livery Stables. Been in the tropics for the last five years, racing, and owing to a badly bowed tendon he was broken to harness.

On Monday, 9th March, 1914, I was called at 11 a.m. to come and see Balbek at once, as he was very sick. I at once went to the stables, and found him down on his side and blowing: temperature 109.

Tried to get him on his feet, but of no avail. The ice depot is only a stone's throw from the stables, so I got ice and kept it on his head and spine, and set him up on his chest, and kept fanning him. Gave the following dgt. :—

Tinct. digitalis	3j.
Liq. Ammonia acetatus	3ij.
Spts. Aeth. Nit.	3j.
Aqua	Oj.

In half-an-hour the temperature had gone down to 108½. With the aid of a sling and several able-bodied men, I got him raised from the ground, and sent on eight men to rub down his legs and body. After a few minutes' rubbing he was able to stand with the aid of the sling and the men steadying him. By the evening the temperature had gone down to 105. Saw him next morning at 5 a.m., temperature 103, and had him led out and grazed for a few minutes. Was put into a comfortable loose box, and in a few days was all right again.

Though I have been in the tropics now for eleven years this is only the second case of sunstroke I have seen; and it is the highest temperature I have ever recorded. I hope this will interest some of your readers.

SENSITIZED OR SERO-VACCINES.

The principle of immunity against pathogenic bacteria is a very complicated subject, and so far as our present knowledge goes is but imperfectly understood. We do know, however, of the phagocytic action of the various body cells and of the so-called "immune bodies"—opsonins, agglutinins, bactericidins—as being prominent factors in the immune role. We know of no agent, or agents, capable of stimulating into activity the former—and I would include in this assertion the much over-lauded preparation, nuclein—but we can by

artificial means exercise very great influence over the latter by raising the content of the body fluids in "immune bodies" either by injecting sera known to be rich in anti-bodies—sero-therapy—or by stimulating the healthy tissues themselves to elaborate immune bodies by the injection of devitalised bacterial emulsion—vaccine therapy.

Sero-therapy, when first introduced, certainly presented great prospects and considerable future utility was anticipated by its devotees. As time went on, however, many difficulties had to be overcome, some of which, unfortunately, were unsurmountable, while, in addition, in several instances the limitations were so pronounced as to render the treatment of little or no practical value. Among the several drawbacks the following may be mentioned:

1. Antisera, as a rule, are rich in antitoxin, but contain few, if any, opsonins, bacteriylins, etc., consequently the most we could expect after injection is the neutralisation of the free toxin circulating in the body fluids *pro. tem.*, while the bacteria at the foci of infection were left undisturbed to elaborate more toxins. Moreover, antitoxin is rapidly passed out of the body, and this partly accounts for the comparatively short period of immunity enjoyed after injecting an antiserum.

2. Sera procured from one animal and injected into another of a different species is more likely to produce, under certain circumstances, hyper-sensitiveness (anaphylaxis) than serum derived from the same species, which is not always obtainable.

3. Difficulty in obtaining sera with a high content, and the depreciation of these with keeping.

4. There are so many types of bacteria even of the same flora, and the immune bodies of the one type may be quite useless when required to wage war against the bacteria of another it must follow, therefore, for a serum to be of any practical use at

all it should be very highly polyvalent, and as many of the sera used to-day are, I fear, more *commercial* than *therapeutical* adjuvants, they should have a stamped guarantee placed on them so that the practitioner and his patient could be guarded by using a standardised serum.

Vaccine-therapy. The limitations and failures of sero-therapy cleared the way for the advent of vaccine-therapy, which, as we now all know, is more than a problematical question, having already taken a high position in curative and prophylactic medicine, with an assurance of a still more prominent position in the future when better understood.

Within recent years Ehrlich showed that when a specific anti-body is brought into contact with its corresponding protoplasmic element the latter becomes fixed to the former. If, therefore, a vitalised streptococcal emulsion for example is mixed with an anti-streptococcal serum the bacteria of the emulsion and the anti-bodies of the serum become bound together, and the combination thus produced is known as a *sensitized* or *sero-vaccine*.

A *sensitized vaccine* consists therefore of a specific bacterium firmly bound to its corresponding anti-body.

To produce such a vaccine one must have an anti-serum possessing not only the suitable anti-bodies but also in sufficient evidence. It therefore follows, for reasons already stated, all anti-sera should be standardised, and if this is true in *serum* therapy it is even more so in *sero-vaccine* therapy.

It is obvious the bacterial emulsion must be pure for, if alien pathogenic bacteria are present they will be left free in the sera, and if injected into the animal may lead to local or general infection, nothing but pure cultures should therefore be used.

The emulsion having been standardized it is mixed with the serum and left in contact from 12

	(1) Serum.	(2) Vaccine.	(3) Sero-vaccine.
Nature of immunity	Passive antitoxic	Active antibacterial	Active antitoxic and antibacterial.
Degree	Limited, Proportionate to dosage	Dependent on dosage and intervals, but may rise very high	Said to be higher than (1) or (2).
Rapidity of production of immunity	Rapid. Immediate if intravenously given	Delayed	Rapid
Permanence of immunity	Slight (2 weeks at most)	Considerable	? Probably between (1) and (2).
Local reaction	Great, varying with dosage	Variable; dependent on dosage and vaccine; may be <i>nil</i> .	Inconsiderable or <i>nil</i> .
General reaction	May be considerable, chiefly dependent on nature of antitoxin	Variable, chiefly dependent on dosage	Almost <i>nil</i> .
Focal reaction	May be marked, as with diphtheria antitoxin, but often slight	Always present if dosage sufficient and efficient.	Probably as with (2).
Possible ill-effects	Serum sickness, rash, urticaria, anaphylaxis	Dependent almost entirely on dosage, with proper dosage <i>nil</i> , except in rare cases where urticaria or rash	<i>Nil</i> .
Applicability	Limited	Wide	Limited.

to 24 hours; centrifuged, and the resultant precipitate washed with saline solution to remove undesirable contained elements.

After the lapse of six to nine months the bacteria tend to desensitize, becoming then a source of danger.

Alcock, Besredka, Levy and others have injected into animals a lethal dose of virulent pathogenic bacteria, followed by the injection of the corresponding sensitized vaccine and these animals have either lived longer than the control animals or survived altogether.

Sensitized vaccines from what has been stated would appear to be indicated (a) in specific infections which tend to become generalised, causing dissolution by toxæmia (b) in epidemics of influenza, strangles, and pneumonia, (c) In old standing cases where vaccine therapy has failed to clear the focal area even after the exhibition of large doses, in short in those cases where the system has developed a pronounced toleration to vaccines.

In these latter class of cases sensitized vaccines in the limited number of cases I have used them, have given me favourable results. These I hope to record at a later date. I append an interesting comparative table of serum, vaccine, and sero-vaccine drawn up by Dr. Allen.

ABSTRACTS FROM FOREIGN JOURNALS.

A CASE OF TETANUS.

Eisenmenger records (*Bulletin de la Soc. Centrale de Méd. Vét.*), the case of a horse which received a blow with a whip handle upon the right eye. This caused a small wound, which was not treated. Eight days later the animal showed a certain depression and an impairment of masticatory movements, resembling "sleepy staggers." The next day the right eye seemed to be rigid and immovable, the pupil was somewhat contracted and did not react to light. The eyelid hung loosely downwards. The skin of the head retained its sensitiveness. The tongue was hanging out of the right side of the mouth. The gait of the horse was normal, and the tail was not held stiffly.

On the following day the left eye had also become immovable, its eyelid was relaxed, the horse had difficulty in mastication, and a pronounced tetanus developed.

Treatment consisted in injections of antitetanin, clysters of ether and chloral hydrate, and the administration of strongly alkaline fluids by the mouth. After two days an improvement appeared, and the eyes became movable again. A speedy recovery followed.

The author remarks that the chief interest of this case is the rarity of the eyes and muscles of the eyelids being involved in tetanus.

The case confirms the results of Brunner's investigations in 1894. Brunner found that the

muscular concentrations always begin on that side of the body upon which the inoculation of the virus has taken place, and that the degree of severity of the symptoms depends upon the virulence of the poison, which in strong doses causes paralysis. This explains the paralysis of the eyelids in the present case.—(*Berliner Tier. Woch.*)

THROMBOSIS OF THE ANTERIOR AORTA IN A HORSE.

The following unusual case is recorded in the official veterinary report of the Bavarian Army for the year 1912. The subject was an eight-year-old mare, serving in a heavy cavalry regiment. In December, 1911, this animal showed slight disturbances of the movements of both fore limbs. These gradually increased, so that the mare found it difficult to rise from the ground. On January 1, 1912, she fell, and showed great pain, violent sweating, and great weakness. Early the next day her condition was the same; but in the afternoon complete paralysis of the fore part of the body appeared. The mare rose up upon her hind limbs and pushed the body forwards, so that the fore feet came to lie between the hind limbs. An affection of the central nervous system or a thrombosis of the vessels supplying the fore limbs was diagnosed, and the mare slaughtered.

The post-mortem examination revealed thrombosis of the anterior aorta and its branches.—(*Münchener Tier. Woch.*)

DIFFUSE SUBACUTE MENINGO-ENCEPHALITIS IN A DOG.

Roquet and Sellier record (*Journal de Méd. Vét. et de Zootechnie*) the case of a dog, which had distemper about the age of nine or ten months. Later, at the age of a year and a half, the animal showed a vesiculo-pustular cutaneous eruption and symptoms of gastro-enteritis.

From this time forth the dog gradually lost condition, and showed paresis of the posterior part of the body. This was accompanied by inco-ordination of movement, causing an unsteady staggering gait, with giving way of the limbs. Paraplegia then appeared, coincidentally with a certain rocking movement of the head.

Soon afterwards dysphagia appeared. The dog was no longer able to swallow, for the movements of the tongue and lips were abolished. For four days he remained completely voiceless from the labio-glosso laryngeal paralysis. A slight improvement then set in, in consequence of subcutaneous injections of strychnine sulphate, physiological serum, and camphorated oil. The paraplegia was also treated by electricity, and by point-firing upon the loins.

The medullary paralysis afterwards spread to the anterior part of the body, and the fore limbs began to give way. Motor disturbances then appeared in the right eye. The eye was withdrawn to the base of the orbit and showed internal strabismus, and at the same time spasmodic contractions of the eyelids and grinding of the teeth appeared. Towards the end of the illness the mind

became greatly impaired, and the dog finally died in a state of coma.

Post-mortem, a slight intra-meningeal serous exudation was found. The arachnoid and pia mater were slightly iridescent, and showed a very clear vascular arborisation. They only adhered very slightly to the cerebral cortex. The lower part of the brain showed a marked fluctuation to palpation, and, upon section, it was found to be only two or three millimetres thick, in consequence of dilatation of the lateral ventricles by a serous accumulation. Sections of the cerebral parenchyma showed congestion of the finest capillaries, which appeared like bright red specks.

The cerebellum and its pia mater were very congested. The white and grey substance of the cerebellum, like that of the cerebrum, was beset with small dark-red punctiform spots. The spinal cord showed the same lesions.

A histological study of the lesions demonstrated the existence of a diffuse subacute meningo-encephalitis.—(*Annales de Méd. Vét.*)

W. R. C.

LIVERPOOL UNIVERSITY VETERINARY MEDICAL SOCIETY.

[NATIONAL V.M.A.—NORTHERN BRANCH].

A meeting was held on Friday, March 20th. There were present:—Messrs. J. P. Heyes, President; A. B. Mattinson, E. J. Burndred, J. B. Wolstenholme, H. Holroyd, J. Maguire, J. R. Barker, T. S. Atkinson, G. H. Locke, Hy. Sumner, W. Woods, F. S. Warburton, and J. Share-Jones.

Visitors: Messrs. R. Finch, W. J. Young, J. D. Whitehead, J. W. Proctor, and K. Jones.

On the motion of Mr. Wolstenholme, seconded by Mr. Mattinson, the minutes of the previous meeting having already been printed and circulated were passed as read.

The SECRETARY intimated that letters of apology for absence had been received from Messrs. W. A. Taylor, of Manchester; W. J. Fletcher, of Wrexham; and J. Storrar, of Chester.

The PRESIDENT: Is there any member desirous of making any observation on the coming election of Council R.C.V.S.

The SECRETARY: I don't know whether the members present know how we stand in regard to this matter. At our last committee meeting we decided that Mr. Henry Sumner be the representative of this Society, although I think if we ask him Mr. Sumner will explain how we came to that decision.

The PRESIDENT: Our committee agreed, as the Secretary has pointed out, to support Mr. Sumner's candidature, and we want this Society to approve of their action, or if they have any reason for not supporting the committee this is the meeting at which we ought to confirm or rescind the decision of the committee. We have nominated Mr. Sumner for a seat in the Council, and we ought to do our best to secure his return to that body.

Mr. LOCKE proposed, and Mr. Wolstenholme seconded, that the committee's action in nominating Mr. Henry Sumner be confirmed. The resolution was carried unanimously.

Mr. H. SUMNER: I appreciate again very highly the honour you have done me in accepting me as your candidate for election to the Council. It is not the first

time I have received the honour, and I might just make some little explanation as to the reasons which induced me to accept nomination for election. It may be within the knowledge of some of you that about February papers go out to foreign voters, and it is desirable in the best interests of those wishing to get elected that the names should be received before the issue of the papers to foreign voters. Consequently I presumed, on the good fellowship of my friend, Mr. Wolstenholme, who was the original nominator, and who was again good enough to offer my name as a candidate. I need hardly express the great satisfaction it has given me, and my readiness to do my utmost according to my ability, to advance in every way the welfare of our profession. (Applause.)

Another point is this. I think the Committee of this Society agreed to combine, as heretofore, with the Lancashire, Yorkshire, and Eastern Counties Societies in forwarding the candidature of a joint nominee.

The PRESIDENT: I think that is understood. It has not been mentioned at this meeting. We combined before, and I am glad you have called my attention to the fact. Though I did not mention it, we shall expect to work in conjunction with the Lancashire, Yorkshire, and Eastern Counties Societies.

TUBERCLE INFECTED MILK AND TUBERCULOSIS.

Address by Prof. BEATTIE.

Mr. Chairman and Gentlemen,—When your Chairman came to see me he said he wanted me to speak especially in relation to one subject, because a certain amount of discussion had taken place, and certain correspondence had appeared in the newspapers, and an address which was given in relation to the question as to whether tuberculous milk was really a serious menace. Curiously enough, I gave a paper on another subject last night, and this question was raised by a medical practitioner, and therefore I am all the more pleased to be able to give my opinion here.

Another question which was also in the correspondence was, "Are the disadvantages associated with sterilised milk, etc., etc." On that point there are statistics given by various people which are somewhat contradictory, but a prolonged investigation, which has been carried out upon this subject shows there are undoubted disadvantages in the use of ordinary sterilised milk. Yet these are comparatively unimportant. Sterilised milk has been used for years both in Germany and France, and diseases which are supposed to be associated with it, are not more prevalent in those countries than in this country, where it has not been used to the same extent.

For some time we have been dealing with this subject at the laboratory to find a special method, and I don't want to say very much, because my report on the subject was recently considered by the Health Committee of the city, and I am very glad they have agreed to my suggestion, and circulated it with the whole of the details of that method, and it will soon be published.

The only point is, it is supposed that in boiling milk, and in ordinary sterilised milk, certain elements of the milk are destroyed. In the method of electrical treatment, they are not destroyed. No unbiassed observer who has worked, at any rate in the out-patients department of a particular children's hospital, could for a moment dispute tuberculous mesenteric glands and milk supply.

Many of you have been able to explain cases in your experience. Personally, I know of two among my own personal friends where evidence was absolutely clear of tuberculosis developed through no other source than the

milk supply. It is true that everyone drinking tuberculous milk is not infected with tuberculosis, but it is equally true that everybody drinking typhoid infected water is not infected with typhoid. To me it is just as absurd to argue—because some people have drunk milk and not got tuberculosis, that tuberculous milk is quite safe, and even as some people now assert, a desirable article of diet.

Now I want to talk particularly to-day on the work which was published by Dr. Mitchell in *The British Medical Journal* of Jan. 17th this year, which is one of the best pieces of work done on the subject for years.

Dr. Mitchell examined 72 consecutive cases of tuberculous cervical glands in children, not cases that were picked out, but consecutive cases, as they came to the hospital, and he found that in 65 instances (90 per cent.) the bovine bacillus was present, and in 7 cases (10 per cent.) the human bacillus. He decided this by the inoculation of rabbits. It is most striking if you examine the age periods. Up to the age of three years children largely fed on milk, the statistics show that 25 out of 27 cases had showed bovine infection, and the other 2 human bacilli—one a baby of 5 months only—and had been breast-fed by a mother who had tuberculous disease. The other was 10 months, breast-fed for three months, and the father treated for pulmonary tuberculosis during the last ten years.

Practically at that period we have 100 with bovine tuberculosis and 2 infected with human. Of these two cases no history of tuberculosis in the family. Later ages, from 9 years to 12, the differences are not so marked. From 9 to 10 there are three infected with human bacilli, and seven infected with bovine bacilli. We need not consider these, for it was very obvious at that age there were many sources of infection.

"Now," he says, "as regards the bovine cases, it seems more than a coincidence that in not a single case was there a history of pulmonary tuberculosis. In 16 cases, however, one or more of the other children in the respective families were affected with various forms of surgical tuberculosis.

"It is worth while quoting one case of a child aged 5 months which had bovine bacilli. A brother aged 3 years had a tuberculous cervical abscess when the patient's glands were first noticed. I investigated the milk supplied, and found that a cow with advanced tuberculosis of the udder had been removed for destruction in September, 1910. I have not the slightest doubt that its milk was responsible for these two cases of tuberculous cervical adenitis.

"Then another case, which was a child aged two years, fed on unsterilised cows' milk. A brother, 18 months old, died from tuberculous meningitis in 1909. The patient's glands appeared in December, 1910. I found the milk was obtained from a byre situated just beyond the city boundary. I visited the byre, and the dairyman readily confessed that he had disposed in October, 1910, of a very tuberculous cow with the udder involved.

"Another case of a child, aged four years, fed on unsterilised cows' milk. A sister, aged two years, had her tonsils removed (one month after the patient's glands were excised) and there was no clinical evidence in her neck of cervical lymphatic tuberculosis; but from these tonsils Dr. Mitchell isolated bovine bacilli. The family consisted of two children who had been given plenty of unsterilised cows' milk.

"Another case of a child, aged 3½ years; a sister, aged 10 years, had her tonsils removed three months before the glands of the patient were excised. Again there was no evidence in the neck, and bovine bacilli were again isolated.

"Now further examination of the family history gives a very sad record indeed. Take these cases for example. A child 2½ years of age is breast-fed for 12 months, then

is fed on unsterilised cows' milk, and it developed tuberculous glands in the neck from which bovine bacilli were isolated. A brother, six years old, died from generalised tuberculosis, and a brother, five years old, has tuberculous cervical abscesses. These developed three months after the first appearance of the patient's. About the same period there developed a number of cases without any tuberculosis in the family history. Absolutely nothing—except a child fed on unsterilised cows' milk.

"Then there was the case of a child, aged two years, fed on unsterilised cows' milk, had a brother, nine years old, die from tuberculous meningitis, and a sister, five years old, had a leg amputated for tuberculous disease. Another sister, 17 years old, died from generalised tuberculosis, being primarily in the cervical glands."

And so it goes on. A number of these cases where the children were infected in the glands without any special family history of tuberculosis. Now and then the evidence is very strong, but when we come to the milk supply we find the evidence still stronger.

Dr. Mitchell, in all this work, has not only gone extremely fully into the investigation of individual cases, but he has gone to the dairies and investigated the milk supply. Now before I refer to this, let me say that there is a difference in the observations of different observers. The paper quoted, which I referred to, published by Mr. Stiles and Dr. Fraser, in which they got 67 consecutive bone and joint cases in children—these did not correspond, for example, with the German statistics in bone disease. In the German statistics the majority of them are of the human type. That is a significant fact, because in Germany sterilised milk has been used for a longer period than in this country. A recent report of the Local Government Board by Dr. Eastwood and Dr. Griffiths, also show statistics which are a sort of intermediate between the Edinburgh and the German statistics.

Last week I had staying with me a Pathologist from the Children's Hospital, Edinburgh, and I asked him his experience. He said that 80 per cent. of the post-mortems he had were tuberculosis of the mesenteric glands, and in those cases where he had examined he found the bovine type of bacilli in all cases. Now, of course, the explanation of that is perfectly safe; because an investigation of the milk supply—and I think I can say so as one who owns Edinburgh as my old University—in Edinburgh is a disgrace to the country. It is not microscopically examined, and no inoculation work is done. Recently, an investigation has been carried out by the Medical Officer of Health, and he has gone more thoroughly into it than before, and he found that in the byres there were a number of tuberculous cows. In 1912 he removed from the 76 byres in the city 23 distinctly tuberculous cows. How many more there may have been we do not know.

When we come to examine the milk we find some interesting facts. In the first place he says 84 per cent. of these cases were children under two years of age, and were nourished from birth with unsterilised milk. We know, of course, that an uncreasingly large proportion of Scottish babies are bottle-fed. Then, as evidence in favour of the view that the ingestion of tuberculous cows' milk is an important cause of surgical tuberculosis in children, he records several cases, some particularly striking. One case of a country child, aged nine months, was operated upon at the Children's Hospital by Mr. Stiles for multiple osseous tuberculosis. The father and mother and the other children were all healthy. The milk was obtained from a small farm in the village. Investigating the milk supply of this patient, he discovered that of the six cows in the byre two had tuberculous udders, with the milk from both teeming with tubercle bacilli—and a child of nine months has been fed particularly with this milk.

Then another one. A surgical out-patient of the Royal Hospital for Sick Children, suffering again from multiple tuberculosis of the bones, elicited the following: The baby had been bottle-fed with milk obtained from a small dairy farm. The mother had been informed by the child's grandfather, who worked on the farm, that soon after the birth of the child one of the cows had gone wrong! The animal had rapidly wasted, and became so weak that it was unable to stand—it was actually milked lying on the ground, and this milk was used for human consumption. By this time it was thought expedient to call in a veterinary surgeon, who, finding the animal suffering from generalised tuberculosis with marked involvement of the udder, at once ordered its destruction and burial. In both of these cases the bovine type of bacillus was isolated.

Then another case. A child aged six years. A swelling appeared suddenly on the right side of the neck, an abscess formed, pus swarming with tubercle bacilli. Sternal-mastoid muscle extensively involved by the tuberculous process; right faucial tonsil slightly enlarged and showed a dirty surface. The patient usually had unsterilised cows' milk at every meal. Daily supply of milk to the house about two gallons, and obtained from dairy farm where twenty cows were kept. Byre visited in December, 1912, and it was ascertained that a case affected with generalised tuberculosis (lungs and udder involved) had been removed from the byre for destruction in October, 1912. This cow had been in the byre and used for milking purposes for about four years. He isolated the bovine type of tubercle bacilli from both the cervical glands and from the enlarged tonsil.

Some time ago Mr. Stiles was asked to see a baby which the mother thought was suffering merely from the effects of teething. The child was found to be suffering not only from tuberculosis of the bones of hands and feet, but also from tuberculous disease of the upper jaw, of both frontal bones, and of the cervical and mesenteric glands. No operation was recommended. Death occurred six weeks later from tuberculous meningitis. The parents were both free from tubercle, as also were the other children. On inquiry into the milk supply, Mr. Stiles was informed that two cows were kept on the Home Farm for the special use of the household, that they had both been tested, and that neither of them had reacted to the tuberculin test which had been applied six months previously. He suggested that they were probably too tuberculous to react, and that the best plan would be to kill them. This was done, with the result that both cows were found to be suffering from general tuberculosis, and that one of them had a tuberculous udder. In this case it is evident that the cows were so extensively tuberculous that they failed to respond to the tuberculin test.

Here you have a case in which the actual infection has been traced directly to the milk supply, and I have given this particularly. Dr. Mitchell's case I know is well worked out, and how thoroughly he has gone into it. I should like to say that in my own experience in that hospital the story was exactly the same. It was distressing to find the number of cases of tuberculosis—particularly of the mesenteric glands—which came in to die, and when the case was investigated, over and over again it was the same story that was told. These children were fed on unsterilised milk.

I want to say one word in regard to the advantages which accrue from tuberculous milk. It has been asserted by Mr. Mond in his address that it was desirable to give tuberculous milk in order to confer a certain amount of immunity. But that is mere assertion; it has not been proved by any facts. Supposing we admit it for the sake of argument. There are, first of all, factors such as the number and virulence of the tubercle bacilli in the milk, which you are using.

Secondly, the susceptibility of the individual to whom you are going to give it. In addition, I want to know how are you going to test either of these factors. We have no means of ascertaining the susceptibility of individuals to tuberculosis. We know in a general way of certain families which apparently get tuberculosis more than others. We do not know the reason why they should. We do not know why small doses of tubercle bacilli should be beneficial. We do not know the number of tubercle bacilli in any special sample of milk. We may find the bacillus if we examine more carefully.

In microscopical examination we may be able to ascertain the number and virulence of the bacilli in any given sample of milk, and, therefore, if we are going to use this immunising process, it seems to me a more logical procedure to do your immunising by known doses.

We may be told that a patient here and there who has got rabies (?) rendered immune to human bacilli, but for the one treated there may have been 25, or perhaps 50 killed.

Even with the lower animals, we are not sure of the immunising process. Surely it is irrational to do that with human beings, whose lives are being sacrificed by experiment in the practice of this alone.

It seems to me absolute folly to say we should use tuberculous milk, but some people take tuberculous milk with impunity. Personally, I should hesitate very much to drink milk which I knew to be infected.

Statistics which they give by Ralph Vincent of the Infants Hospital in London say he did not bother about tuberculous milk. The whole object is to get clean milk. Personally, if I had my own way, I should abolish the sterilising of milk and give a clean milk supply. Even if I could do that I am afraid of the impossibility of living in an ideal state. We would have to educate the dairymen before that, and even then I should certainly still say that we must be extremely careful about our tuberculous animals, to effectually get rid of tuberculosis. There is undoubtedly danger, therefore we must take all the precaution necessary; whether by sterilising or not, to get rid of tuberculosis in our cattle.

DISCUSSION.

MR. BURNDRED: Mr. President and gentlemen, I should first like to extend my personal thanks to Prof. Beattie for the splendid way in which he is helping us in performing our duty to the public. It seems to me that the experts of professional bodies in England in the past have not sufficiently made public their views on these matters. Unfortunately up to the present time the Tuberculosis Order coming from the Board of Agriculture did not seem to be helping the public forward. For instance, each month they publish statistics of cases reported of all grouped as cases of tuberculosis—they are not divided up into different classes—tuberculosis with emaciation, tuberculosis of the udder, and so on.

In passing, I should like to mention a case which occurred to me which emphasised the necessity of being careful in using the tuberculin test. This week my attention was drawn to a cow in one of the lairages. I examined it very carefully and found it badly affected with tuberculous peritonitis, and I decided to inject 5 c.c. tuberculin, and take the temperature at 6, 9, and 12 hours. I may say the temperature was quite normal at the commencement. At the end of six hours it had risen to 104.79: at the twelfth hour it had dropped to 102. But I instructed the inspector to take further readings of the thermometer. In the meantime the owner suggested the cow should be sent out and fattened as it had been on poor pasture, and did not look as well as it should. However, the animal was slaughtered and it was found to be absolutely covered with both new and old lesions, and that particular discharge—not very

common in bovine animals—from the lungs which denotes T.B. It seemed to me to practically prove the fact that you can get reaction in advanced cases if you give large enough doses.

With regard to tubercle infected milk, not knowing Prof. Beattie was reading this paper I tried to find out if this was dangerous, and what amount of it was present in England at the present time, so we should know where we stood. The London County Council gave the proportion of such milk at 10 per cent., which seems to be the average practically all over the country. One of the authorities took samples for animal inoculation, and got the enormous percentage of 22—double the percentage for England and Wales.

Another point arises, probably through the Board's pamphlet—a lot of people are saying that tuberculosis of the udder is usually, or almost invariably, present only in aged and obviously affected animals.

Some years ago in Derbyshire I remember seeing a heifer in the first milking with induration of the udder, which I had passed over as probably being non-tuberculous. The control came back positive. The cow had only calved four months, and there was slight induration at the back of the udder; yet a very large number of bacilli was seen on microscopic examination. In this, as in previous cases, there was very little tubercle in other parts of the body, but the udder in this particular case was badly affected.

Last year I accompanied a friend from Sheffield on a visit to Derbyshire, and investigated the milk supply from the factory there. Some of the big factory people take the milk from a big district and mix it up in large vats before sending it out to the different districts. We got a sample from one such factory which was tuberculous. We examined 860 cows and found three of them affected with tuberculosis of the udder.

In Blackburn, 28 cows out of a total of 400, or 7 per cent., were found to be affected with tuberculosis of the udder. Mr. Lloyd, in his annual report for Sheffield for 1911, gives definitely the number of cases of tuberculosis of the udder as 3.5 per cent.

With regard to the microscopical examination of milk, personally I agree with Prof. Beattie that microscopical examination should be supplemented by inoculation. I think I remember having seen in one of the medical journals cases of milk being examined where acid-fast bacilli were found.

Mr. EATON JONES: My experience is pretty much the same as others. We found just the normal proportion in Liverpool. I think the most important thing is that all representatives should be able to examine microscopically. In quite a number of cases ordinary mammitis has been present, and in several cases of microscopical examination of the milk we found tubercle bacilli.

Mr. WOODS: So far as I am concerned, I don't think this is really the place to discuss this question, because Prof. Beattie is preaching to the converted. Yet it seems to me to have great value for one special reason. There have been so many loose statements flying about the country lately with regard to the dangers from tuberculous milk, or even the value to be derived from tuberculous milk, and of course, naturally, those people chiefly concerned in the matter are the people who produce milk. You find a large number of children suffering from tubercular diseases where the type of bacilli is the bovine type. I think that is worth a great deal more than any fears one may have.

With regard to the effect of immunising, the game is not worth the candle. Is there anyone—any father, except perhaps an odd crank, who would submit his child to this treatment in practice? For one who holds that opinion you would find 99 who would absolutely refuse to allow it for a moment. When it is argued by farmers that there is no danger because certain people have written very strongly that there is no danger, we

have our answer in statistics. There is a danger, and a considerable danger.

Mr. WOLSTENHOLME: I would just like to say one word with respect to my feelings in this matter. I think Professor Beattie has rendered not only to us, but to the public and to the nation, a profound service by showing the fallacy of these statements which are being made. It seems to me nothing short of criminal folly that people who know nothing at all and have no means of ascertaining the truth should go about making these statements. Sometimes a man gets it into his head that it is harmful to his child to have it inoculated against smallpox. I could not help reflecting on one passage spoken by Prof. Beattie, of how many people must drink water infected with bacilli of typhoid without becoming infected. There was another instance in my mind. I have known of a large number of carcasses of animals either died or killed immediately before death from anthrax, which had been sent to the market.

I think our friend voiced a matter of some importance, certainly one with which I agree with him, that our medical authorities, in my opinion, scarcely get sufficiently in touch with the public to put before them definite evidence of any particular matter which they may have not only in regard to the question of tuberculosis, but in nearly every other thing which is commenced. Writers on radium treatment, for example, literary men with brains, who know nothing at all about it, are writing up this treatment. If we had more public audiences attending University lectures in important centres on subjects of this sort—which is far more important than lectures on the French Revolution, the public could come into contact with medical men who could give definite facts regarding any matter of most striking importance to the nation.

Prof. SHARE-JONES: I would not like this discussion to close without adding a word of congratulation to Prof. Beattie. I have observed with some alarm these statements which have been made so frequently in the lay press by irresponsible gentlemen, and intensified by the unfortunate fact that one or two very respectable papers—respectable in the ordinary sense of the term—have taken the matter up, and are rather inclined to support these gentlemen, and that this should come in a moment after some years of work on the part of bacteriologists, human and veterinary, to raise the unthinking public to a frame of mind when they may be regarded as a thinking public, and knock on the head the old antipathy to bacteriology, that a statement of this kind should be now issued broadcast, is nothing short of a tragedy. I quite agree that it is rather a pity some publicity could not be given in the lay press of the scientific denunciation of the statement which has been presented to us. I regard Prof. Beattie's scientific denunciation of it as incontrovertible evidence. There would be no getting out of it for them if some publicity could be given to such an address as we have heard today. Personally, I feel more grateful to him every day. Mr. Wolstenholme suggested that public lectures should be given. Well, I come from Wales, and it has been our national memorial to the late King Edward to stump the country from one end to the other on this question of tuberculosis, and what surprised me has been the ready manner in which people have accepted information on the subject. If a campaign were commenced in England with the same vigour as in Wales both the public and the medical profession would benefit.

The PRESIDENT: Before closing the discussion, I should like to make an observation or two on my own experiences of tuberculosis. I realise that I have not the opportunities that some of the whole-time inspectors have; but we men who are in practice do get an opportunity of seeing a large number of cases of tuberculosis,

and some cases which inspectors do not encounter. We are called upon to treat animals with various infections, and amongst them we frequently realise that we have a case of tuberculosis to deal with which the owner does not suspect.

One point in Prof. Beattie's paper interested me very much, and that was the possibility from the evidence he showed, of the transmission of this disease from the bovine species to the human. I think that many veterinary surgeons will agree that we in our practice if we have been at all observant, have evidence that the disease is communicable from one species of animal to another. I think many of us have satisfied ourselves as well as we can, with the powers at our disposal, that the bovine animal has been the means of supplying the organism which has set up the disease in another species of animal. I have encountered frequently tuberculous mesenteric glands, particularly in horses that have been given large quantities of milk owing to illness.

I have in mind two cases of tuberculosis in horses where the disease has been manifested in other organs, and I have felt in these cases that they had received the infection from cattle, because at some period of their existence they had severe illness, as in the case of the Belgian horses referred to, and been fed with milk containing tubercle bacilli.

I think it is common knowledge to all medical and veterinary men that small doses of the virus is calculated, if given judiciously, to afford certain immunity.

When I commenced to study veterinary science it was known, and had been for many years, that in cases of rabies, attenuated virus could be given. Since then the immunizing of human beings and other animals against attacks of disease has become a big scientific business, and to-day we realise it is a matter that has to be proceeded with on very careful lines. We do realise its value, but we also realise it is a matter with which we ought not to recklessly tamper.

Prof. BEATTIE: Gentlemen, in the first place I want to thank you heartily for the way in which you have received the paper. I think it would be a very good thing if the medical profession and the veterinary profession could be brought more closely together than in the past. I am sure it is becoming increasingly important that those working the Public Health Service—the medical health officer, biologist, and veterinary surgeon shall work in conjunction. In regard to some of the points raised, I am extremely interested in the one regarding the rise of temperature following injections with tuberculin in advanced cases of tuberculosis, where there was a rise of temperature in the short period of six hours, and the temperature down in nine hours. I should like if somebody could get information on the point where in cases injected with tuberculin and no reaction, whether you did not get a rise at that early period. My reason for asking is that some investigations of Dr. Pinfold (?) have shown that you get a rise of temperature to 104 or 106 if you take the temperature an hour or an hour and a half afterwards. If you don't you find nothing at all occurs. Some of these temperature records which have been mentioned in connection with toxins have been perfectly erroneous, you can get them with distilled water. And, further, he showed that if you diluted your toxin (?) you got a bigger rise in temperature than when concentrated.

Then there was the case of tuberculosis (?) without any definite lesions. I think these sort of cases do occur. We have, curiously, recently had two cases; one in a herd of 21 cows. Milk was sent in the ordinary routine, and a very careful examination was made, and there was only one cow in that herd which was at all suspicious—the others were declared to be perfectly free. A sample was taken from the suspicious case, and a sample taken from the others—I think that is an extremely important point—and the result was the suspected cow

showed no evidence, and the other was tuberculous. Then the cows were divided up into batches of four, and from all these four we found tuberculosis.

Again, these cows were examined very carefully, and still the veterinary inspector said he could find no tubercle till we took further samples and we were able to separate the cow in each case. Unfortunately the matter here was outside our area.

In another case of exactly similar nature, the animal was slaughtered. In that case I asked specially that the whole of the udder should come to us. I cut it into the smallest pieces and in only one extremely small piece, which I thought was somewhat suspicious—on making a section I found a typical tuberculosis nodule.

Then the question of microscopical examination and acid-fast bacilli. This acid-fast bacillus occurred in a specially selected sample. One case that has been published and specially referred to in which acid-fast bacilli was not only present in the milk, but was found in the guinea-pig. In inoculation in the guinea-pig there was nothing suspicious. We examined microscopically, I don't think there was any tubercle, although we found acid-fast bacilli. We carried it further. We grew it and found it grew perfectly well. Since that period it has been puzzling us all along, until yesterday we have come to the conclusion that we have definite evidence that it is another very like tubercle but proves to be not tubercle.

I still hold that microscopical examination of milk alone is extremely dangerous. Even with efficient inspection by veterinary surgeons you run a risk of some of these cases being missed.

In regard to the same sample of milk being reported by one authority as tuberculous, and by another authority as non-tuberculous, I should not like to say anything unless I knew the method used, and the quantity of milk used, as that is a great factor in this matter. It is not a case of the method adopted not being a good one. I always recommend a considerable quantity of the milk and the whole of the deposit to be stirred up and then inoculated.

One or two have raised the question of publicity of these things. I think it is a great pity that we in the medical profession are so absolutely tied down by the restrictions of the General Medical Council.

The PRESIDENT: I would like to take this opportunity of moving that a hearty vote of thanks be accorded to Prof. Beattie for giving us this interesting address. When I asked him to give us a lecture he did not hesitate a moment when he heard the kind of lecture we wanted. We have had him here on several occasions, when he has given lectures which have been of great value to us, but in my opinion this last lecture is of quite as much importance as any he has ever given, and it is given too at a very opportune time when almost everybody in the country of average intelligence is greatly interested in the subject of tuberculosis. It has come at a time when statements are being made throughout the country by first one and another observer, and by people who make observations from many different points of view and proceed in a variety of ways. When one has to consider human and other animal life, the people whose observations surely are of the greatest value are those who specialise in work of that kind.

In Prof. Beattie we have a specialist who is more than ordinarily interested in the particular subject that he has been dealing with to-day, and he seems to infuse enthusiasm in the minds of members of our profession when he comes into contact with them, and he is always interested in any case of tuberculosis in the lower animals brought before him. I have been for some time associated with work that is being done in that direction by Prof. Beattie, and I have also seen the great work going on at the laboratory. He has been most

anxious to assist me in obtaining a thorough knowledge of the disease, and enabling me to make such examinations as are necessary and desirable. I am certain that it is of great value to veterinary surgeons to be able to come into contact with men like Professor Beattie to help us, and we are greatly indebted to him. Unfortunately we have very few men in our profession who have the opportunity of doing work such as he has to-day. Consequently, if we had to rely on the assistance of the members of our profession only, I am afraid that our information would be somewhat limited, so that on that account we ought to be doubly thankful. With these few remarks I beg to move that a hearty vote of thanks be given to Prof. Beattie.

Mr. WALKER: I have great pleasure in seconding the vote of thanks, and I am sure we are all indebted to Prof. Beattie for his excellent address. I may say that I think it was the feeling of the Committee when we decide to approach him it was with the view to getting

him to deliver an address which would give the lie direct to Dr. Mond. I look upon this as a national matter, and as regards publicity, this lecture will, of course, be reported in *The Veterinary Record* and *The Veterinary News*. With regard to publishing it in the lay press, we could do it through our Society along with his report on the sterilization of milk. I think that would probably get Prof. Beattie out of his difficulties in regard to the question of etiquette of the medical profession.

Prof. BEATTIE: I simply again thank you very heartily. It is a pleasure to me to do this, as it is a subject in which, as you know, I am particularly interested. I feel strongly in regard to these statements by absolutely irresponsible people, which may do enormous harm, and anything I bring before the Society, the Society is at liberty to use it as it likes.

A. WALKER, F.R.C.V.S., Hon. Sec.

 Note.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

(NATIONAL V.M.A.—IRISH BRANCH.)

The annual general meeting was held in the Gresham Hotel, Dublin, on Thursday, January 29th, Mr. P. J. Howard, President, occupied the chair, and there were also present:—Messrs. Watson, Heney, Wilkinson, Patrick, Doyle, Prentice, McKenny, Reavy, Healy, Purcell, McCann, Col. Moore, and Professors Dunne, Craig, and O'Connor.

The PRESIDENT: Gentlemen, up to the present the minutes of the last meeting have not been circulated, but they will be in due course.

Mt. WATSON: I beg to propose that they be taken as read.

Mr. PATRICK: I beg to second that.

There being no objection the minutes were signed by the Chairman.

Prof. O'CONNOR announced that letters of apology had been received from Messrs. T. D. Lambert, Dunlop, Winter, Hare, Taylor, Thompson, Shearman, Ross, Kerr, Dobbyn, Chambers, Jarratt, Nolans, Mahony, McGuinness, and Preston.

The SECRETARY announced he had received letters of acknowledgment of votes of condolence from Miss Hunting, Mrs. Thompson, and Mrs. O'Reilly.

The SECRETARY: With regard to the Hunting Fund I just want to say that we have received a letter from Mr. Macqueen and Mr. H. Gray—Mr. Gray is Treasurer and Mr. Macqueen is Chairman—and it asks us to subscribe towards this very deserving fund.

REPORT OF COUNCIL.

The SECRETARY read the following report:—

A meeting of the Council of the V.M.A.I. was held on Thursday, Jan. 15th. There were present: Mr. Patrick in the chair; also Messrs. McKenny, Wilkinson, Watson, Dunlop, Holland, and Professors Craig and O'Connor.

Minutes of the previous meeting were read, confirmed, and signed.

Apologies for non-attendance were received from Messrs. Reavy and Heney.

A letter from Mr. Power was read with reference to fees under the Tuberculosis Order, 1913. Mr. Holland undertook to write to Mr. Power drawing attention to the scale of fees drawn up by the Association in May, 1913, and approved by the D.A.T.I.

A letter was read asking for a subscription to the Hunting Fund. A subscription list was opened by Messrs. Patrick, McKenny, Dunlop, Wilkinson, Watson, and Professors O'Connor and Craig, each subscribing one guinea.

It was arranged to hold the annual meeting, to be followed by the dinner on January 29th. The Hon. Sec. and Mr. McKenny to make arrangements for the dinner, and Mr. Heney to be asked to undertake the musical programme, a sum not exceeding four guineas to be allowed Mr. Heney for this purpose.

The following accounts were passed for payment:—
Reprints £2 5s.; Clerical assistant half year £5;
Secretarial expenses and postage £3 10s. 7d.; Engraving of medal 2s. 6d.

In addition to those eligible for re-election the following Vice-president and Members of Council were nominated:

President: Mr. Reavy, proposed by Mr. McKenny, seconded by Mr. Holland.

Vice-Presidents: Mr. Wilkinson, proposed by Mr. Watson, seconded by Mr. Dunlop.

Members of Council: Mr. Carr, proposed by Mr. Russell, seconded by Prof. O'Connor; Mr. Prentice, by Mr. Watson, seconded by Mr. McKenny; Mr. Barlow, by Mr. Wilkinson, seconded by Mr. Watson.

It was proposed by Mr. Watson, seconded by Mr. Wilkinson, and passed, Mr. McKenny objecting, that Rule 9 be amended as follows:—

RULE 9.

"Each member shall pay in advance an annual subscription of half-a-guinea (10/6), which shall fall due on the first day of January in each year. No member shall be entitled to exercise any of the privileges of the Association who shall be in arrear with such subscription."

Amendment.—To add the words—"and in those cases in which the subscriptions are in abeyance for 3 years, the membership will automatically cease."

Mr. McKENNY: I was very sorry I had to oppose that, the rules as they stand at present have been considered from time to time, and that rule has received very great consideration. As the rule stands at present, if anybody is in arrear the Treasurer has to submit it to the Council. At the meeting the Treasurer told us that there was one gentleman who had paid him three guineas, six years arrears. I think you mentioned another, and even the amount of four guineas has been paid. The suggested addition to the rule, in my opinion, would not only unwisely tie the hands of the Council in this matter but would render the rule ambiguous, inasmuch as the addition would make it imperative that a member whose subscriptions remained unpaid for a given period *ipso facto* would cease to be a member of the Association, whereas the rule as it stands gives the Council discretionary power in dealing with members whose subscriptions are in arrear, therefore we stultify ourselves if we add the suggested addition to the rules—I may also state that rule No. 10 would become obsolete if the suggestion is adopted, as its utility would be destroyed. I don't know, but I think that after the matter was discussed Mr. Watson, who proposed it, was not very strong on the point himself. However, he stated it was a thing he only suggested, and that it would get full discussion at this meeting.

Mr. WATSON: I don't wish to take up the valuable time of the meeting, considering our annual dinner comes on immediately this meeting is over. Mr. McKenny objects to my amendment, but then Mr. McKenny generally finds himself in the unfortunate position of opposing everything he does not father (laughter). Now as a matter of fact these rules have been in existence for a great number of years. They were principally drawn up and promulgated by Mr. McKenny and the late Mr. Hedley. I am responsible for some small amendments, and the one Mr. McKenny hangs his case on was drawn up by me. The Treasurer gave us at the last Council meeting some instances of members who paid their subscriptions after the lapse of three or four years.

Mr. McKENNY: And six.

Mr. WATSON: He did not tell us how many have gone into eight or ten years and have not paid. I think if the rules were carried out as they stand they would meet the requirements of the case. But as a matter of fact we know they have not been enforced, and I think it is time that some rule should be introduced that would provide that membership should automatically cease, say at the end of three years, if the subscriptions are not paid. I should like to know the number of stamps paid in respect of members who have not paid for six or seven years. I think my suggestion would meet the requirements of the case instead of writing to them. If this rule came into operation members would soon realise they automatically cease to be members of the Association if they do not pay their subscriptions.

Prof. CRAIG: I want to propose that this amended rule be adopted with the proviso that it shall come into force at the beginning of next year. This will give members who are in arrears an opportunity of paying the arrears of subscriptions. If they do so, then we can hope for a good balance in hand at the end of the current year.

Mr. WATSON: I have no objection to that amendment.

The PRESIDENT: As Mr. Watson is agreeable, and as it will not come into operation for another year, I think it might be well to refer it back to the Council.

Mr. McKENNY: The Council really are tying their hands. You will find it better to leave our hands free. That was under discussion before.

A MEMBER: And still the money is due.

Mr. WATSON: We shall have under discussion Prof. Craig's report, and perhaps it would be unfair to anticipate it. We might get some information from Prof. Craig's statement on our financial position.

The PRESIDENT: The matter might be amicably arranged at the Council meeting.

Mr. WILKINSON: Why not decide it now when there are so many members present?

Col. MOORE: It seems to me that the man who does not pay up in three years ought to be struck off.

Mr. WATSON: There are members in arrear for eight years.

The SECRETARY: Are they worth considering?

Col. MOORE: I should make it a rule that any man who was in arrear for three years should cease to be a member.

The PRESIDENT: Would you strike him off automatically, or have each case considered by the Council?

Col. MOORE: I should say that a man who does not pay for three years does not wish to be a member, and that he has ceased to take any interest in the Association.

The PRESIDENT: Better decide the matter now by having a vote of the members present. It is further amended by Prof. Craig that it does not take force until January, 1915. The question is whether we will have that rule amended as suggested or leave it—as Mr. McKenny wishes—in the hands of the Council to consider the list of defaulters.

Col. MOORE: May I make a suggestion? Do you think anyone would pay £10 and become a member for life? Or £5, that is tantamount to ten years. That would considerably relieve the burden of a standing subscription of 10/6 a year, which is somewhat of a nuisance.

The PRESIDENT: That would be quite under a different heading from the present motion. I think it a very good suggestion, and you could propose that the Council should consider it at the next Council meeting and give their opinion as to whether it should be a rule. But in connection with this present matter the question to be decided is whether we will have this amendment of Mr. Watson's made, or Prof. Craig's, or whether we

will have the rule as it is—that we consider the question of defaulters from time to time. We will vote on Mr. McKenny's amendment. Does anybody second Mr. McKenny's proposition that the rule should be left as it is? [There was no response.]

The PRESIDENT: I regret, Mr. McKenny, that you are not on the winning side to-night. Mr. Watson's amendment of Rule 9 is passed, but it does not come into force until 1915.

Messrs. Doyle and Patrick were appointed scrutineers of the voting papers for the election of officers and Council for 1914.

Examined and found correct,

Jan. 21, 1914. JOSEPH H. WOODWORTH, F.C.A.

Prof. CRAIG: I refer you to the column in which the moneys that we have invested are noted. You will notice that there are two small paragraphs. The first one refers to the amount of money we have paid for certain stock, etc. The bursary money is invested in Consols. In the second paragraph the same stock is put down, but at par value. The reason for doing that is that after the late Mr. Hedley's death the moneys had to be transferred from the joint trustees to Mr. McKenny and the par value only given.

For the stock there is £4 4s. 8d. in dividend, and of that dividend one-fourth is added to the bursary account. The bursary account is intended to enable a medal to be presented to the College for competition by the students of the final year. There is nothing further I think that requires to be noted in reference to the bursary account. In the general account, first, there is the reporting of meetings. Last year there were five meetings—there was an extra meeting in connection with the transfer of the College. The item of law costs is an account we had with our solicitors which extended from 1906 to 1911, and had to deal with some investigations, such as the McDonnell case in Dublin, and also in connection with counsel's opinion in reference to the Finance Act and relative to the rebate on the Motor Tax and our position as medical practitioners. This year we have given our first contribution to the National Veterinary Medical Association, we having now become affiliated with that Association—and you will notice the contribution is £3 10s. The contribution is put down at one shilling per head, and we record 70 as the active list of our members. The "deputation expenses" were in connection with certain deputations that were sent to the Department. Mr. Watson had a lot to do with that. Subscriptions: You will notice the subscriptions for 1913 were £32 16s. 6d.—that is to say that something like 65 members paid their annual subscription. That is not what it should be. The membership of the Association is something between 135 or 140, and yet less than half of them have paid their annual subscription. No doubt we also obtain a good revenue from arrears, but I think it would be much better for the Treasurer if all subscriptions were paid annually and not allowed to go into arrear at all. An odd subscription of three or four guineas is very welcome, and I hope that when this new rule is put in force it will allow of all the subscriptions being paid. Occasionally a subscription is paid in advance. If you find there are some points in the balance sheet which are rather hazy and which require further explanation I shall be glad to give it.

Perhaps I may refer to the dividend received. Last year this amounted to a little over £3. One of the quarterly dividends has not yet been received, and I don't think we will get it now. I think it must have gone astray during the late Mr. Hedley's fatal illness.

Mr. HEALY: Do you give any grant to the International Congress?

Prof. CRAIG: No, we deferred that at the last meeting to the beginning of this year.

Mr. WILKINSON: I beg to propose that the balance sheet be accepted.

The SECRETARY: I beg to second that.

The motion was put and passed unanimously.

The PRESIDENT: Before we leave this question of the Treasurer—who has all the money—we might consider the matter that was referred to this meeting from the last one about our further subscription to the International Congress.

Mr. REAVY: With your permission, Mr. President, I would like to ask a question, it looks like one in geography. Do the members who have charge of the International Veterinary Congress know there is such a place on the map as Ireland, or that we have a Department of Agriculture, or that we have veterinary officers

attached to that Department? It seems strange to me that in not one section have they appointed an Irishman. True, the Royal Veterinary College of Ireland is represented by the Principal. Why Irishmen should be so completely ignored I am at a loss to know, the only way they seem to remember us is to take our subscriptions.

Mr. HEALY: I agree with you. I don't see why the Irish Department of Agriculture should not be represented. Whether that is due to laxity or what on our part I do not know, but I think it is time the matter should be remedied. There is no general practitioner going over to attend the Congress. I think that at least one member should attend. Mr. Howard has got a new position, and I think he has plenty of time on his hands. I say it is hard lines that we have to supply money and not get proper representation.

Mr. McKENNY: Might I say that this may be considered another injustice to Ireland, and that perhaps we might take advantage of it. I am not inclined for Home Rule for Ireland from one point of view, but perhaps we might take advantage of it now. The profession in Ireland has not been consulted in this particular direction. Why the profession in this country should have been treated in this way I do not know. But as regards being on the Council of the R.C.V.S. I think that is our own fault. We did put up from this Association two members and they got in.

Mr. WILKINSON: And they never attended. Oh, yes, Mr. Byrne did.

Mr. McKENNY: I would like that at our next general meeting we should put forward Mr. Watson and Mr. Howard. If they would accept the office I am certain we would be well represented.

Mr. HEALY: Why not have them elected at the next Council meeting in June?

Mr. McKENNY: Yes. Mr. Watson, would you consent?

Mr. WATSON: I went up for a contest of this kind before and got very badly mauled. (Laughter.) I don't want that repeated, but now that I am on my legs I want to tell you I met Mr. Howard at the last annual meeting of the National, and he is a most popular man of Irish descent. I have not got the slightest doubt that if you put forward Mr. Howard he will be triumphant at the poll. I really think Mr. Howard is the man.

Colonel MOORE: I happened to be at the meeting in connection with this International Congress last week, and I think there is some mistake. I don't think the Council want to put a slight on Ireland at all. They intend to approach the Department of Agriculture and the Royal Dublin Society. The matter was talked of at the meeting, so I think that perhaps we are going a little too far. I was not told who was going to read a paper from Ireland, but I think they want the assistance of the Department of Agriculture anyhow.

Mr. HEALY: It is only in the discussion the representatives from Ireland will appear—Prof. Mettam and Prof. Craig.

Mr. REAVY: As far as I can read from the Veterinary Press you are debarred. My recollection is that it was suggested some steps should be taken, but the matter was closed and nothing was done. I don't know whether anything has been done, but evidently they can take our money—but they won't take anything else.

Mr. WATSON: If it would not be too late I would like to propose that the name of our friend Mr. Prentice should go forward. I have known Mr. Prentice for a number of years, and I must resent his hiding his light under a bushel any longer. I think it is time he took his stand for Ireland. He occupies a leading position in connection with the Department of Agriculture, and I strongly urge that his name be sent forward.

Mr. PRENTICE: I have not the modesty that Mr. Watson ascribes to me. I anticipated that my Depart-

ment would be represented as any other Corporation will be represented. Therefore I don't think there would be any use in now allowing my name to go forward at all. The door is closed.

Mr. REAVY: I think it would be an insult to the Department of Agriculture and to Mr. Prentice if we proposed his name.

The PRESIDENT: The way I look at it is this, that owing to the absence of a regular representative on the Council of the Royal College in London, where this thing was first considered, there has been a possible oversight, and that Ireland has—if you like—been forgotten. Our position is that we have given a subscription, and that we have promised a further subscription. I am sure that if our Secretary only intimates when that subscription is being sent that they have quite forgotten to pay the necessary compliment, it will be quite sufficient. As I say, it was simply owing to thoughtlessness there was no Irishman present at that Council meeting. Of course it looks bad when they applied for our money and got it. I took it from reading *The Veterinary Record* and *News* that they were applying for delegates. But outside any Society, we of the veterinary profession should have been considered, and the least compliment that could be paid us was that some Irish practitioner should have been put on. I am sure the matter is an oversight, and that if attention is drawn to it it can be remedied. I am sure that what Mr. Reavy means is that the profession in Ireland should be represented on the Executive Council or whatever high authority has the management of affairs.

Mr. REAVY: I cannot understand why the veterinary staff of the Department of Agriculture was forgotten, because the English Board of Agriculture is well represented. Manchester is represented by its Veterinary Officer of Health as well as two or three other places in England and Scotland. They forgot we have the same officers in Ireland.

The PRESIDENT: It is quite possible that the Dublin Corporation have already applied.

Mr. REAVY: These men are on the different sections and I cannot understand why they forgot the Department of Agriculture.

The PRESIDENT: Let the Board of Agriculture stand by itself. I say the veterinary profession should be considered. The Board of Agriculture will be sure to get its head in somewhere—Mr. T. W. Russell or someone else.

Mr. McKENNY: No representative from Ireland has been appointed at all. I think we would be stultifying ourselves by drawing any attention to the matter at all. Our report will appear in the Veterinary Press. We have promised them money; let us send it and have done with it.

The PRESIDENT: Why send them money at all?

Mr. McKENNY: We promised it, and it is in a good cause to the whole veterinary profession.

Mr. HEALY: Would it be well to find out whose fault it is in not having representation from Ireland?

Mr. REAVY: I think it reflects on the profession in Ireland.

The PRESIDENT: Does anybody propose that we should take any particular action?

Mr. REAVY: It is too late. Treat it with silent contempt.

ELECTION OF OFFICERS.

The PRESIDENT: Of course, as you are already aware, Mr. Reavy has been unanimously elected as President. (Applause.)

The Vice-Presidents will be Mr. Dunlop and Mr. Wilkinson. (Applause.)

The New Members of Council will be Messrs. Heney, Reavy, Magee, Prentice, and Carr. (Applause.)

The Secretary has been given a further year, and the Treasurer has also got home. (Applause.)

Before we leave I wish to congratulate our officers for the coming year, and I hope that under their care and management our affairs will prosper. (Applause). I also wish to thank the members of the Association for the very great consideration they have given me during my time. (Applause).

On the motion of Mr. Watson, seconded by Mr. McKenny, a cordial vote of thanks was passed to Mr. Howard, and the proceedings terminated.

THE ANNUAL DINNER.

The chair was occupied by Mr. P. D. Reavy, the new President, and there were also present: Col. J. Moore, A.V.S., J. McCann, J. F. Craig, G. T. Dunne, P. J. Howard, D. S. Prentice, J. Doyle, W. C. Patrick, W. H. Wilkinson, J. McKenny, W. H. Bradley, J. Holland, L. M. Magee, J. F. Healy, F. A. Heney, J. J. O'Connor, A. Watson, M. Purcell.

Visitors: J. R. Ellison, M.R.C.V.S., W. J. Byrne, W. Usher, G. Beckett, F. Jeffs, F. Horner, J. R. Morgan, J. D. Cope, V. Sanderson, G. Haines, M. Trench, J. Whitmore.

Apologies: E. C. Winter, T. D. Lambert, J. B. Dunlop, J. B. Hare, F. W. Taylor, J. K. Thompson, F. J. Shearman, J. J. Ross, F. Kerr, A. Dobbryn, W. Chambers, G. H. S. Jarratt, J. Nolans, B. P. J. Mahony, J. Preston.

After dinner, which was excellently served, the toast of the King was musically honoured.

The PRESIDENT proposed the health of the Past-President, and said: You all know what a good fellow he is, and what he has done for this Association. It is not necessary for me to say anything in his praise, beyond this, that during his year of office the affairs of the Association could not have been better looked after. (Applause).

The toast was enthusiastically received, "For he's a jolly good fellow" being sung.

Mr. HOWARD, in responding, said: I have to return you my very sincere thanks for the kind way in which you have drunk my health. I can assure you that it was with no small misgivings that I undertook the honourable position of President of this Association. I felt my position all the more difficult by reason of the fact that a splendid man filled the chair previous to myself. I was only a very humble country practitioner—(No, no)—and I felt I was assuming a load I would not be able to carry. But, thank Heaven, the time has come when I am relieved of the burden. (Laughter). I hope sincerely that the Association is at all events no worse off than when I took up the reins of office. (A Voice: "It is all the better," and applause). I honestly endeavoured to do my little best. (A Voice: "And you succeeded.") Well, if I have been a success it must be mainly attributable to the kind co-operation I received from every member of the Association. This evening, at our annual meeting, we were considering a grave question—that is, what we suffer owing to our not being directly represented on the Council of the Royal College of Veterinary Surgeons. It is unfortunate that such a state of affairs should exist or should be allowed to exist, because there is no doubt that the profession in Ireland ought to be represented. (Hear, hear). But there is this difficulty—when men who are millionaires in Dublin treat their profession with silent contempt and do not see their way to lose time and money attending meetings in London, it is scarcely to be wondered at that the country practitioner cannot afford to attend. I am awfully sorry that I could not afford it. If I could I would willingly do the work, or anything I could to benefit the profession in Ireland. But I don't think that any practitioner in Ireland should put himself out and attend meetings in London. It might be possible in a few years more of progress that the Association might be able to purchase an

aeroplane without much trouble or expense. (Laughter and applause). [A Voice: And insure his life.] (Laughter.) Well, the veterinary surgeon's life is not worth much. But I want in conclusion to thank you for all the kindness and assistance afforded me during my year of office, and I can only express the hope that this Association will continue to prosper under the guidance of our esteemed new President, Mr. Reavy. (Loud applause).

The CHAIRMAN gave the toast of "The Army Veterinary Corps," which was worthily honoured.

Colonel MOORE in responding, said, when I came here to-night I did not know that I would be expected to make a speech, otherwise I should have had one prepared. As a matter of fact I should really have been in Aldershot to-night. That is now my station, but having to move house and home, I find myself in Dublin and have come along to join you. [A Voice: "We are glad to have you," and applause]. Gentlemen, I thank you for having toasted the Service to which I belong, and for having associated my health with the toast. During the past few days you have noticed that the War Office has adopted the expedient of advertising the Army in the newspapers, and I may therefore be excused if I follow suit and say a little bit about my own Service. You know that the Army Veterinary Service is divided into several sections. We have a regular Army Veterinary Service, a Special Reserve, a Territorial Force Service, and lastly young contingents of Officers Training Corps. Our regular Army Veterinary Service consists of about 170 officers, and these officers are distributed for duty in the United Kingdom, South Africa, India, and Egypt. If we went to war the number that would be required would be very large—more really than the Army Veterinary Service can supply. We have to find ways and means to supplement our regular officers; and for this we have the Special Reserve in the first instance. I am glad to say that this Special Reserve during the last few years has taken on very considerably. It is a service of civilians to whom commissions are granted. The Army trains them for three months, after which they return into civil life. They get a retaining fee of £20 a year up to the age of forty and are given £40 for outfit, that is for uniform. I cannot conceive why more young men don't rush at it, because it is a very good thing. I am very glad to say though that it is progressing. I take a personal interest in it, and I trust I may elicit your support in helping it on. A fair number from Ireland have joined. The third branch is the Territorial Veterinary Service. We have no territorials in Ireland. During the last few weeks in Aldershot we have had a class of territorial officers, and I was surprised at the advance that has been made. The officers' regular service dined with them one evening and all sat down in mess kit. This in itself is a sign of the progress that has been made. Then the last and youngest of all services is the Officers Training Corps. The idea of a veterinary contingent was conceived in this country. Prof. Mettam, Prof. O'Connor, Prof. Craig, and Prof. Dunne are members of it, and it is an excellent little contingent—none better. The value of the officers training contingent is not only one of veterinary service, but is a training for the youth to be good fellows, to cultivate gentlemanly ways, and so on. It also carries a potential sort of benefit to the Army. I have enumerated all these sections in detail because collectively they mean a great deal. I believe we will never excel in the Army unless we can make ourselves big. The more we collect these sections together into one large whole the better chance we have of making ourselves known, felt and appreciated. The Army Veterinary Service has progressed since the Boer war. We were hopeless then, but we have pulled ourselves together, and are now going along like a house on fire. I am certain if we

ever came to war again we will render very good service, and a very good account of ourselves. Again I thank you for having drunk my health. I take great pleasure in being a member of this Association in Ireland. I am very sorry I have to leave after three very happy years, but I suppose, being a soldier, I must move on. In any case, I shall always look back on the pleasant days spent in Ireland in connection with this Association of which I trust I shall continue to be a member and come to see you occasionally. [A Voice: "We will always be glad to see you," and applause].

Mr. WATSON: I give you the toast—the very important toast of "The Department of Agriculture," and particularly of that branch that is presided over with such dignity by the Chief Veterinary Officer, Mr. Prentice. The department is a most important factor in the progress of Ireland. Ever since Mr. Prentice has become chief inspector improvements have been made in every direction. At the same time anyone who knows the Department of Agriculture, knows that the department and its representative officers are the best abused men in Ireland. (Laughter). If you go down to any part of Ireland and happen to mention any member of the department you will be lucky if you are not stoned out of the town. (Laughter). But after all the veterinary branch have done excellent work for Ireland. Why should not the department be an important body, considering that Ireland is not a manufacturing country? We hear about the introduction of Home Rule and of the blessings that would flow from it—industries would grow here and blossom there; but it is my opinion that Home Rule or no Home Rule Ireland is bound to remain an agricultural country, and the most important feature will remain—the live stock. And the live stock is largely looked after by the officers of the department. Some of the improvements that have been effected have been made in the breeding of thoroughbred stock. I think my friend Mr. Bradley will admit that the thoroughbred stock in Ireland has improved by leaps and bounds within the last ten or fifteen years. Therefore I think we have every reason to be proud of the Department of Agriculture. I couple with the toast our old friend, Mr. Prentice. (Applause).

Mr. PRENTICE in responding, said: Like Colonel Moore, I did not expect to be asked to reply to a toast, but our Chairman is very urgent. I represent more especially the veterinary branch of the Department of Agriculture, and I think I can claim that some progress has been made by us. Recent events have caused it now to have an augmented and a re-organised veterinary staff. We don't intend to stand still; we intend to progress. I suppose we have sixty veterinary surgeons, some of whom have been with us for 30 or 40 years, but the great majority of them are new comers. The Department of Agriculture has the ruling voice in the appointment of certainly over 160 veterinary surgeons in this country. We have had recently in Ireland outbreaks of foot-and-mouth disease, which did not appear for 28 years previously. That malady has awakened us to new energy. I might here say we propose to provide an extensive laboratory, and I know that veterinary surgeons, especially such as local authority veterinary surgeons should take advantage of that laboratory.

Then I might refer to one disease which breaks out in dairy yards—I mean contagious abortion. We invite you to diagnose this contagious abortion as it affects dairy cows. We receive, as is done by the English Board, blood from the supposed affected animals and we inform the owners—and I trust we will be able to inform the veterinary surgeons—whether these animals are so affected. Hitherto we have been able by using a vaccine, known as anti-abortion, to inoculate a considerable number of dairy cattle with re-

markably successful results. All I would ask is that in sending us material for this test known as the agglutination test—that thoroughly aseptic measures be adopted, otherwise it will do us or the veterinary surgeon no credit. Having gone into that small item, I can perhaps only say that in the Department of Agriculture the veterinary profession has a strong friend in this country. It takes the greatest interest in the veterinary profession, especially in the veterinary surgeons whom it in a measure controls, as it does in the case of local authorities under the Diseases of Animals Acts. I don't know whether I would be right here in urging one point on veterinary surgeons who are veterinary inspectors. There was a time, we all know, when examining sheep for sheep scab—unfortunately a very common disease—sufficient care was not exercised, and only a casual examination was made. Now we recognise that we must go more deeply into the disease if we are going to eradicate it. I again thank you on behalf of the department. (Applause).

Mr. PATRICK proposed the toast of "The Royal College of Veterinary Surgeons," and said: The financial conditions of the College are unfortunately not as good as they might be, and we must all regret that its efforts are hampered by want of the sinews of war. The profession has been appealed to and has responded fairly well in different quarters. We all deplore the loss of the late Mr. Hunting—a very distinguished member. We had the Annual Meeting and Dinner in Dublin two years ago, and it was pronounced to be one of the best and most successful functions ever held in Ireland. I hope it won't be long before we have them in Ireland again to show how we appreciate that body. (Applause). The toast was cordially received.

Professor CRAIG, in responding said: This toast is generally associated with the name of a member of Council, and I am sorry to note that no Councilman is present. In the circumstances it would have been more appropriate if one of the gentlemen of those whose names were proposed as candidates for the Council of the Royal College of Veterinary Surgeons at the General Meeting had been called upon to respond to this important toast. I was glad to notice that the toast was honoured very heartily, because it shows that the Royal College, although its headquarters are situated in London, has a warm place in the hearts of its graduates in Ireland. It would certainly be much better for the members of the profession here in Ireland if we had more representatives on the Council. Mr. Howard has told us the disabilities under which a practitioner in Ireland suffers in acting on the Council. Unfortunately, the funds of the College are not in the condition in which we would like them to be. At the present time they are gradually dwindling, and it may soon be that the College will be in a bankrupt condition. But I hope the members of the profession will stand to the College and see it does not go under. It is the only portal by which members can enter the profession in the British Isles, and I hope efforts will be made to preserve it. I was also glad the toast was received so heartily, because I take it as an agreement with the policy of the Council. One of the complaints made is that the Royal College does not take sufficient interest in cases which are brought under their notice for investigation and prosecution. We know that on several occasions this Association has sent some cases of infringement on our domain to the College, but that the College decided that it was unable to take action on account of the absence of sufficient available evidence. To my mind the College could have come to no other conclusion. An adverse decision would do an infinite amount of harm to the profession. Perhaps when the Amendment Bill is passed, which is so necessary for the very existence of the College, the Council will be able to defray the expenses of its members, and thus remove the disabilities attached to the office for an Irish

member, and it will certainly be in a stronger position to maintain the rights of the profession and prevent any infringement on its domain. We trust that time will soon come. In conclusion, on behalf of the Royal College of Veterinary Surgeons, I desire to thank you for the hearty way in which you have received this toast.

Professor O'CONNOR: I think nothing remains for me except to endorse what Professor Craig has said, and to thank you on behalf of the College for having honoured the toast so heartily. (Applause).

The CHAIRMAN proposed the toast of "Our Guests," which was responded to by Mr. Haines and Mr. Whitmore.

Mr. WHITMORE proposed the health of the Profession in Ireland, which was responded to by Mr. Watson and Mr. Bradley.

Mr. PRENTICE: I wish to propose the health of Mr. Reavy, the new President. Personally, Mr. Reavy and I have been old friends for upwards of thirty years, and I have never known anything about him that was not to his credit. He has now entered on his year of office as President of this Association, and I have no doubt that when it terminates we will all be in a position to congratulate him for what he has done. Naturally he states he has a very rough road to travel, seeing that so many eminent men have travelled it before him. But I have no doubt he will follow worthily in their footsteps. Without saying anything further in regard to Mr. Reavy, I ask you to drink his health.

The toast was enthusiastically received.

The PRESIDENT: Gentlemen, I have to thank you for the hearty way in which you have received the toast proposed by Mr. Prentice. I have also to thank you for electing me to the position of President of this Association. It is the highest honour you could have bestowed upon me, and I feel very proud of it. On looking over the roll of Past Presidents, it makes me feel quite nervous to think that I could attain the same good results for the benefit of the profession as they have done; I have a fair amount of cheek, but not enough to think I could ever follow in their footsteps. One thing I can assure you, gentlemen, I have the interest of the profession very deep at heart, and anything I can do to promote its interest, will be to me a labour of love. I hope at the end of my term of office, with the assistance of our worthy Hon. Secretary, Professor O'Connor, and every member of the Association, we will have done something for the betterment of the profession we all love so dearly.

Mr. HENEY proposed the health of "Our Musical Guests," and said they wished to give their hearty thanks to them for having come amongst them that evening. He coupled with the toast the name of Mr. J. D. Cope, and said that owing to an engagement in Dundalk, Mr. W. F. Cope was unable to favour them. He thought they owed their musical guests a deep debt of gratitude. He also coupled with the toast, Mr. Fred Jeffs.

Messrs. Jeffs, J. D. Cope, Morgan and Sanderson responded.

Mr. HENEY proposed the toast of "Our Secretary and Treasurer." In Professor O'Connor they could have no better officer. (Applause). He was heartily interested in the welfare of the Association, and was doing his level best to increase the membership of the Association. That night brought him a great deal of trouble and worry, but he was always able to meet any difficulties. (Applause). He also coupled with the toast their worthy Treasurer. (Applause).

Professor O'CONNOR said he thanked them very heartily indeed for the very kind way in which they had drunk his health. He could assure them it was a very great pleasure to him to do anything he could on behalf of the Association. He considered it a great honour to

be Secretary of the Association. He could not allow the occasion to pass without referring to his able assistant, Mr. Haines, who did the bulk of the hard work. (Applause).

Professor CRAIG was very glad to be able to possess their confidence in looking after the funds of the Association.

In the course of the evening an excellent musical programme was sustained by Messrs. J. R. Morgan, McCann, F. D. Cope, Vine Sanderson, Heney, Wilkinson, Baggot and Fred Jeffs. Mr. Harmer efficiently presided at the pianoforte.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL SOCIETY.

[NATIONAL V.M.A.—NORTHERN BRANCH].

A meeting was held in the Imperial Hotel, Darlington, on Friday, March 13th, Mr. J. M. Walker, West Hartlepool, President, in the chair. There were also present: Messrs. D. R. Dudgeon, Sunderland; W. H. Blackburn, South Hetton; W. Awde, Stockton-on-Tees; P. Snaith, Bishop Auckland; T. Wilkinson, Lanchester; W. N. Dobbing, C. G. Hill, F. H. Sanderson and J. H. Taylor, Darlington.

Visitors: Dr. Hern, Darlington; Messrs. A. G. K. Brittain, Guisbro'; and J. W. Rider, Beamish.

It was proposed by Mr. Dobbing, seconded by Mr. Hill and carried, that the minutes of the previous meeting as they appeared in the *Veterinary Record*, be taken as read and confirmed.

Elections and Nominations. Mr. A. G. K. BRITTAIN, M.R.C.V.S., Guisbro', was elected a member of the Association, on the proposition of Mr. Snaith, seconded by the Secretary.

Mr. J. W. RIDER, Beamish S.O., was nominated by Mr. Wilkinson, seconded by Mr. Sanderson.

Mr. R. BARKER, M.R.C.V.S., Stockton-on-Tees, was elected a member, on the proposition of the President, seconded by Mr. Wilkinson.

The PRESIDENT gave Mr. Brittain a hearty welcome to the Association, and expressed the hope that he would attend the meetings.

Mr. BRITTAIN suitably replied.

Correspondence. Apologies regretting their inability to be present were received from Messrs. H. Peele, J. Wilson, P. B. Riley, T. T. Jack, and E. R. Gibson.

The invitation from the Royal Sanitary Institute to attend the Congress of the Institute to be held at Blackpool from July 6th to 11th, which had been left over from the last meeting was considered.

Mr. HILL spoke strongly in favour of the Association sending a delegate, and thought the profession ought to lose no opportunity of attending such gatherings, and taking part in the discussions, and thus showing to the public generally that veterinary surgeons were quite capable of filling appointments in connection with public health work.

Mr. SANDERSON thought the subject ought to be dropped as he did not see what use could be done by attending the Congress. After other members had expressed their views.

Mr. SNAITH proposed that the President be sent as the delegate from the Association, and that his out of pocket expenses be paid; this was seconded by Mr. Dudgeon and carried.

Mr. WALKER said that he would try his best to be present at the Congress, but being single handed he might find it rather difficult to get away.

THE HUNTING FUND.

A circular letter soliciting subscriptions for this fund was read.

Mr. AWDE said that he had known the late William Hunting for many years and thought the splendid work he had done ought to be recognised in some way. He understood that a movement was on foot to try and get a grant from the public service fund for the benefit of the children of Mr. Hunting.

Several members expressed their appreciation of Mr. Hunting's work, and it was generally agreed that any help to the fund would be best left to the individual members of the Association.

GLANDERS—DISCUSSION OF MR. DUDGEON'S PAPER.

Mr. HILL, who moved the adjournment of the discussion at the last meeting, when the paper was read, regretted that he had not had time to read through Mr. Dudgeon's remarks as he had intended doing. Personally, he had not seen many cases of the disease. He noticed that when the temperatures of the pit ponies had been taken just on coming into the stable from work, according to the observations of Messrs. Dudgeon, Gibson and Blackburn they were often 103°, which was interesting. He took particular notice of what Mr. Dudgeon had said with reference to the mallein test, that it was not safe to give an opinion until 36 hours after inoculation. He felt he must not sit down without thanking the essayist for his interesting and practical paper.

Mr. AWDE expressed his regret at not being present at the last meeting when the paper was read. He had not had much experience of the disease, excepting when at College, where he saw a good many cases. With reference to temperature he had usually found it higher than normal in an animal coming in from work. At present he had under treatment a good many cases of influenza and strangles, and in many of these cases the submaxillary glands were enlarged very similar to what they were in glanders. He was using nuclein in these cases with good results.

Mr. J. W. RIDER said as a visitor to the meeting, he should like to say a few words with reference to the subject under discussion. He remembered 18 to 20 years ago, when a young man, having a case of thick leg with ulceration in a pit pony. A dose of physic was given and the result was that the ulceration was more marked and glanders was diagnosed. The whole of the animals were then tested with mallein and many reacted. In his opinion every animal ought to be tested with mallein before going into the pit. In taking the temperature of pit ponies it was an uncommon thing to find many with a sub-normal temperature.

He agreed with Mr. Dudgeon that it was not wise to give an opinion until thirty-six hours had elapsed after inoculation with mallein. He had known cases where the local reaction was only very slight at the end of twenty-four hours, but at the end of thirty-six hours the swelling was well marked. He once had a case which after inoculation had no increase of temperature, but had a local reaction of 6 inches by 4 inches, and the swelling was three or four days before it disappeared. This animal was tested again, but did not react, but it was destroyed, and on post-mortem nodules of the disease were found in the liver and lungs.

Dr. HERN expressed pleasure at being present at the meeting, and had derived much information from what had been said about the disease. He would like to know if the members thought mallein curative in its action.

He had seen three cases of glanders in human beings which were very puzzling at first to him, and the other medical practitioners at the hospital, and they thought of calling in a veterinary surgeon to consult with them. Specimens were sent up to the Clinical Research, and the report was that they were treating glanders. One patient died and two recovered. All three cases occurred in cases of men working in stables.

Mr. RIDER said that mallein was curative, and this had been demonstrated in his experience. He knew of cases which had been tested 12 or 14 times, and after the third or fourth inoculation no reaction was obtained.

Mr. SNAITH said that up to a month or so ago he was under the impression that glanders in man was incurable, but in a recent issue of *The Journal of Comparative Pathology and Therapeutics* a case was recorded of an Indian veterinary surgeon being attacked with and cured of the disease, but he had to undergo terrible sufferings.

Mr. DUDGEON, in replying, said that he was pleased his small effort had interested the members. With reference to temperatures, violent exertion did undoubtedly send the temperature up, but during his examination of pit ponies he frequently found that when quiet in the stable their temperatures were very often sub-normal, 97°, 98°, 99°, for instance.

As Mr. Rider had told them, it was no uncommon thing to get a good local reaction and no increase of temperature. In making post-mortems of glandered animals, he advised all not to confine their attention only to the lungs when looking for lesions, for these often occurred in the liver and spleen, and were absent in the lungs. If you got a local reaction and increase in temperature, you could depend upon lesions being present. As regards testing, you might not get a local reaction at the 9th to the 15th hour, and he had known of some veterinary surgeons considering this long enough to wait before deciding whether an animal was affected or not, but from his experience he would not give a certificate until after the 36th hour.

In reply to Dr. HERN he might say that mallein was curative, and many years ago a French veterinary surgeon continued testing some army horses until they ceased to react. They were then considered cured of the disease, and were placed alongside other horses which had passed the test, and they worked together for years without any recurrence of the disease.

His opinion was, however, that if you had a reacting animal you had better get rid of it. He had read the account in the journal which Mr. Snaith had referred to, and would send the account to Dr. HERN to read. It was most interesting, but the poor fellow suffered much and lost his arm. He thought he got the disease when experimenting with cultivations.

During the testing of some animals recently he had found the temperatures rather high at the time of inoculation, and in those cases one must rely on the local reaction to a great extent. On March 2nd he tested a pony whose temperature was 103.2° at the time of inoculation, and never got much higher. Another had a temperature of 100.6° at time of testing; nine hours after it was 98.4°, and then gradually went up to 104.6°. The local reaction was only slight and not very pronounced. This pony was retested for the local authority a week later, its temperature was 99.8° at the time of inoculation, 104.8° at the 12th hour, and then gradually came down to normal. The local swelling was not typical excepting for the soreness, and he would like to impress the fact that the degree of soreness was very important, even if the swelling was not a big one. During the time this pony was first tested it was off its feed, but not the second time, but it would have to be destroyed. He thought that the testing done by Messrs. Gibson and Blackburn was easily a record for the North of England. He acted for the local authority in the matter. There were only two or three clinical cases presented to them, and the others would never have been discovered had it not been for mallein which had proved itself absolutely reliable.

Mr. HILL proposed a very hearty vote of thanks to Mr. Dudgeon for his valuable paper, and included in that vote of thanks Messrs. Gibson and Blackburn who had so kindly given their experience of the disease.

This was seconded by Mr. Snaith, and carried with acclamation.

CLINICAL CASES.

Mr. SNAITH exhibited a piece of wood 33 inches long, which he had taken from a colt. The animal had galloped along the side of a fence, and this foreign body had entered just near the first rib, passed under the shoulder blade to about the girth, and when he was called to the animal only about one inch was protruding. There was great lameness at first, but this gradually disappeared. What struck him most was the absence of secondary abscesses.

He also exhibited a mammary gland which he had recently taken from a collie bitch. It was cystic in character, which condition in his experience was rare.

He had recently had an interesting case of what looked like a tuberculous growth in the larynx of a cow. This cow suffered from laryngitis for a few days; it received treatment, and got alright so far as one could see. It had a relapse and got worse, and was eventually destroyed, with the result that the growth which he now produced was found in the larynx, and the lymphatic glands in the chest were affected in the same way. The illness came on quite suddenly which made one first think that some foreign body was the cause of the mischief.

Mr. SNAITH also exhibited a calculus taken from the bladder of a horse, which had been destroyed on account of old age. A large calculus was found in the neck of the bladder, and there was a calculus in each kidney. It was interesting to note that these had never caused the horse any trouble during life, and their presence was a surprise when the animal was slaughtered.

FOX TERRIER WITH TWO AMPUTATED HIND LEGS.

Mr. SNAITH showed a photograph of this interesting case. It appeared that this fox terrier bitch two years ago was caught in a reaping machine and both hind legs were cut off below the hocks. The bitch was a great favourite, and was in pup, so was kept, and reared up her offsprings. By that time the stumps had healed over, and as she managed to get about alright her life was spared. When travelling on soft ground she could put the legs down alright, but if the surface was at all rough or stony she carried her legs under her. He did try a pair of false legs, but the bitch was soon at them with her teeth.

LYMPHADENOMA IN A BITCH.

The SECRETARY stated that he had recently had an interesting case of this disease. It occurred in a Scotch terrier, and was brought to him with the history that for some time she had been losing flesh, and seemed listless and would not eat. The bitch was in an emaciated condition and had a pendulous abdomen, and he recommended the owner to have the bitch destroyed. This was done, and a post-mortem made with the result that the enlarged spleen, which he showed them, was found. This organ weighed 1 lb. 12 oz., and was of a particularly bright red colour, the liver was enlarged and showed signs of softening, but only in the spleen were lymphoid growths found.

PFLANZ'S EMBRYOTOME.

It had been arranged to have on view at the meeting this instrument, through the courtesy of Messrs. A. Favre & Co., Newgate Street, London. It was inspected with much interest by the members, but it was generally agreed that it would not be very practicable for the Association to purchase the instrument.

Mr. DUDGEON proposed a vote of thanks to Mr. Walker for his conduct in the chair. This was seconded by Mr. Wilkinson and carried, and the members then had tea together in the hotel.

J. H. TAYLOR, Hon. Sec. & Treas.

VICTORIA VETERINARY BENEVOLENT FUND

The quarterly meeting was held at 10 Red Lion Square, London, on Thursday, April 2nd. There were present: Messrs. Dunstan, Slocock, Garnett, Spicer, Abson, Sumner, Banham, and Shipley. In the unavoidable of the President, Mr. J. Dunstan in the chair.

Apologies for absence were received from Messrs. P. J. Simpson, H. A. MacCormack, F. L. Gooch, and the President (Mr. R. C. Trigger).

The minutes of the last meeting having been adopted, the Secretary presented his report.

SECRETARY'S REPORT.

I have again been through the grants to our old recipients. Unfortunately, I am not able to give every detail I should like, as it is difficult to obtain replies from my correspondents after repeated endeavours. I may say that, acting on the result of the enquiries made, I feel I should recommend the continuation of the grants to Mesdames J—, G—, C—, G—, E—, Y—, B—, B—, P—, H—, T—, M—, and T—.

The grant to M.—W. can now safely be increased to 10s. per week, and that of Mrs. S— to 7s. per week. I will place before you communications from Mr. Amos with reference to H. Horton, and from Mr. Brown, of Invergordon, with reference to Mrs. S—.

A fresh application has been received from Mrs. T—. I have suggested to the Exor that we endeavour to get the daughter, aged 10, into the London Orphan Asylum. I have received the nomination papers, and have sent them on to the Secretary. I shall be very glad if any member of the Fund who can will help to get this girl elected. I would suggest that a grant of 5s. per week be made to the Exor for the maintenance of the child aged two, and that Mrs. T— be informed that we are unable to do more, and that she should endeavour to obtain some situation.

I am presenting a satisfactory increase in our list of members, and sincerely hope that every effort will be made by the members of the Council to attract new members by indicating to them the good work we are doing, especially pointing out the insufficiency of the grants we are able to make. At the present time our grants to 15 recipients amounts to £288 annually.

I have seen the Secretary of the London Orphan Asylum this morning. He informs me that the nomination has been received, and the election will take place in June. I therefore propose to obtain list of subscribers to the Home, and shall hope that every member of the profession who would be willing to help to obtain votes will immediately communicate with me, I shall be only too happy to send full particulars, cards, and a list of subscribers to the Fund. I am strongly advised that individual efforts energetically carried on will undoubtedly be the means of getting the girl elected. This is a matter of very great importance, as owing to her age this is the last and only chance for her election.

It was agreed that the grants to all the old recipients should be continued, and that the grant to Mrs. W— be increased from 5s. per week to 10s. per week, subject to satisfactory replies being received from correspondents.

It was agreed that the grant to Mrs. S— should be increased from 5s. to 7s. per week.

The action of the Secretary in getting the nomination for the election of Hilda Tait to the London Orphan Asylum was confirmed, on the proposal of Mr. Garnett, seconded by Mr. Spicer.

On the proposal of Mr. Sumner, seconded by Mr. Abson, the Secretary was instructed to send a cheque of £5 to Mr. Amos, of Durban, to be applied for the benefit of Hewitt Horton, for some educational purpose which Mr. Amos considers advisable.

The Secretary presented to the Council for consideration the offer of Mr. E. A. West, to present to the Funds of the Society the receipts for the Sunday exhibitions at a cinematograph show owned by him, the London County Council indicating that the receipts from such exhibitions are to be given to some charitable object. The Council viewed with great pleasure the kind offer, and accepted the same, provided the conditions could be carried through.

List of New Subscribers since last quarterly meeting.

TENTH INTERNATIONAL VETERINARY CONGRESS.

The following ladies have kindly consented to form the nucleus of a Ladies Committee in connection with the Tenth International Congress:—Mrs. Banham, Mrs. Butler, Mrs. Garnett, Lady M'Fadyean, Mrs. Moore, Mrs. Male, Mrs. Mettam, Mrs. Macqueen, Mrs. Price, Mrs. Shave, Mrs. Shipley, Mrs. Slocock, Lady Stockman, Mrs. Todd, Miss Trigger, Mrs. Villar, Mrs. Willett, Mrs. Woods, Mrs. Wooldridge.

The Organising Committee would be very pleased if the various members would be kind enough to ask their lady friends and relations to serve on the Committee and to forward their names and addresses to the Hon. Secretary, at 10 Red Lion Square.

The Committee desire to point out that they have no means of learning, except through members, of those ladies who are willing to take an interest in the Congress, and it is with a view of getting together as representative a Committee as possible that this appeal is made. Names and addresses should be sent forward at the earliest date possible, as it is desired to print them in the programme of the Congress.

It may be pointed out that the duties in connection with the Ladies' Committee will not be very onerous, it will only be necessary to hold a few meetings of the Committee before the Congress for the purpose of

advising how lady visitors can be most suitably entertained.

During the Congress week it is expected that the services of the members of the Ladies' Committee will be at the disposal of lady visitors to the Congress.

On the proposal of the Veterinary Medical Association of Ireland, the following names have been added to the Organising and Executive Committees of the Congress:—

Organising Committee: Messrs. J. McKenny, Dublin; J. Holland, Athy; F. W. Emery, Dublin; J. J. Rosa, Belfast; D. Hamilton, Ballina; J. J. Vahey, Sligo; P. J. Howard, Ennis.

Executive Committee: Messrs. A. Watson, J. H. Carr, W. H. Wilkinson, Dublin; L. M. Magee, Navan.

Board of Agriculture and Fisheries, April 14, 1914.

Light-Horse Breeding.

Some £14,000 a year is being spent by the Board of Agriculture under the scheme inaugurated in January, 1911, for the encouragement of light-horse breeding. In the annual report on the administration of the grant, it is stated that the breeding of light horses has been declining for many years. The increase of mechanical traction is to some extent responsible, but there are other causes, notably the fact that farmers have not found the industry a paying one. The main object of the scheme is to revive interest in the industry, and to endeavour to make it a commercial success.

It is recognised that the market for the "misfit" light horse is daily growing smaller. As a business proposition it does not pay to breed "misfits," but only animals for which there is a good demand at a good price. The hunter is a class to which the latter definition applies at the present time, and encouragement is being given to tenant farmers and others to breed horses of this class. Hunter-breeding does not appeal to farmers as a general rule, unless they are good horse-men. There are, nevertheless, it is stated, many farmers who, without being skilled horsemen, are ready to breed light horses if sufficient encouragement and facilities are afforded them, and if they find they can do so without losing money. Substantial premiums are therefore granted for high-class thoroughbred stallions, and for mountain and moorland pony stallions, while assistance is also given for the purpose of encouraging the breeding of the old Welsh cob. So far the progress made has been satisfactory.

The administration of the scheme is carried out by committees which have been set up in every county in England and Wales, and an Advisory Council has been constituted, on which the various public departments and societies concerned are represented, to advise on the working of the scheme and on horse-breeding matters generally. At one of their meetings last year the Standing Committee of the Advisory Council considered a letter from the Development Commissioners suggesting a reduction of the grant for light horse breeding in view of the expenditure to be incurred on the heavy horse industry.

The Committee agreed unanimously that the light horse industry was in far greater need of assistance than that of the heavy horse, and they considered that any reduction in the grant would tend to militate against the success of the scheme, which must be in operation

for at least five years before any useful conclusions as to its value could be arrived at. They therefore passed a resolution declaring that "So far from being able to reduce the expenditure, the experience of the Committee leads them to think that the grant could usefully be increased, and they are unanimous in thinking that it would be most unwise to divert money from light horse breeding to the heavy horse industry.—*Daily Telegraph*."

Surgery of the Heart.

A *Times* correspondent reports that Dr. Alexis Carrel, of the Rockefeller Institute for Medical Research, who received the Nobel Prize in 1912, addressed the American Surgical Association meeting in New York last week, and described a series of successful experimental operations on the valves and orifices of the hearts of dogs. Fifty distinguished European surgeons were present as the guests of the Association.

Dr. Carrel asserted that some day surgeons will be able to cauterise lesions of the valves in human subjects and repair them as easily, or almost as easily, as he himself has been able to do in experimental operations on animals.

The great feature of the operations is their technique. The chest-wall having been opened, the pedicle of the heart is seized by a dozen forceps whose metal jaws are covered with soft rubber. This shuts off all circulation from the heart itself. It is safe, Dr. Carrel declares, thus to arrest the circulation for two and a half minutes. Dr. Carrel makes an incision in the heart wall 1½ in. long over the operative point. He finds this gives room enough within which to work. Several kinds of operations were performed. The sigmoid valves of the aorta were exposed and cauterised. The contracted pulmonary orifice was cut. The sigmoid valve and the pulmonary orifice were exposed and sutured.

Dr. Carrel found that those operations could be performed with but little danger to the life of animals. Only two of quite a large number died, and the deaths were due solely to errors of technique. The operations were performed in October and November, and the animals are now in a normal condition. Dr. Carrel says that it is undoubtedly possible to perform more complicated operations than those already performed under similar conditions.

Personal.

PARTRIDGE—EDGAR.—On the 9th April, at St. Andrews, Ashley Gardens, W., by the Rev. Prebendary Northcote, W. E. Partridge, son of the late J. T. Partridge, Staff Commander, R.N., to Evelyn Alston Edgar, only daughter of the late Henry Edgar, M.R.C.V.S.

Mr. HUGH L. CHAMBERS, F.R.C.V.S., Banbridge, has been elected a member of the Hunters' Improvement and National Light Horse-Breeding Society.

Mr. WILLIAM ROBB, M.R.C.V.S., has been appointed to act as judge of the Light-footed Horses, and **Mr. HUGH FERRIER, M.R.C.V.S.,** of the Dogs, Collies, and Sporting Class at the Dumbartonshire Show at Dumbarton, on Saturday, May 2nd.

At the Easter Vestry for St. Wilfrid's, Hayward's Heath, held on Tuesday evening, the Vicar re-appointed **Mr. H. TAYLOR, F.R.C.V.S.,** as his warden; and later, he announced that the Easter offertories towards the assistant clergy's stipend endowment fund had amounted to £49 7s. 9d., and £11 more was wanted to complete the £250 now almost raised. He was able to announce that the donor of £100 towards the next £250 was **Mr. H. Taylor.**—*Sussex Daily News.*

CRANFORD.—On the 6th April, at Bangalore, India, of enteric fever, Ethel, the dearly-loved wife of Major R. L. Cranford, A.V.D.

SUITABLE APPLICANTS FOR COLONIAL APPOINTMENTS.

Sir,

In your issue of the 28th of Feb., 1914, "East of Suez" makes a very reasonable appeal for better remuneration for Colonial Veterinary Surgeons, and rightly points out that the "gilded pill" of £300-£400 a year does not at all compare favourably with the salaries paid to the medical and other professions in similar positions, and one could, therefore, hardly expect suitable applicants to be very numerous.

I do, however, not see the necessity of dragging Sir Arnold Theiler and young South African Veterinary Surgeons into the matter. I take great exception to the following sentence in his correspondence: "As a former student under Dr. Theiler, in Pretoria, I cannot seriously believe that he intends to look to young South Africans for assistance in research work in South Africa."

Sir Arnold Theiler has already a few young South Africans on his staff, and I don't see why they should not compare favourably both as regards qualifications and capability with any other class of Veterinary Research Officers.

One should almost think that being born and bred in the country, if anything, should better fit them for Research Work on local diseases.

Yours truly,

24 March, 1914.

SOUTH AFRICAN.

SHOULD LATIN BE ABOLISHED AS A COMPULSORY SUBJECT FOR THE PRELIMINARY EXAMINATIONS.

Sir,

In commenting upon the proposed alterations in our Matriculation Syllabus, you remark that the transformation of Latin from a compulsory to an optional subject is "a rather important change, and there is something to be said both for and against it." Most members will agree with this, but I wonder how many will take the trouble to weigh up the arguments for and against. Not many, I am afraid—there are few professional questions which Veterinary Surgeons generally are more disposed to neglect than those which concern the training and examination of students. Nevertheless, I venture to state my views upon an alteration which seems to me a serious one. I believe that if Latin be made an optional subject, and many students take advantage of the change to enter College without, we shall have made a step backwards.

I entered College more than twenty years ago, under the old three years system. Only one language was then required, and Latin was optional. I chose a modern language, and entered College without knowing a word of Latin. Then I was soon plunged into a maze of new and totally unfamiliar words—words which almost seemed to have been arbitrarily invented to perplex the student—and I have not yet forgotten the difficulties that scientific nomenclature, especially anatomical nomenclature, presented to me. Since qualifying I have learned a little Latin, and I am convinced that my College course would have been much easier had I known it then.

The chief argument used against the retention of compulsory Latin is, I think, that modern languages are likely to be much more useful in after life. I grant the truth of this, especially as regards post graduate professional reading. But there are two considerations which weaken the argument, as applied to our case. The first is that our Matriculation Syllabus already requires two languages—if we continue to compel students to take Latin as one, he can still choose a modern one for the other. The second I put in the form of a question. How many Englishmen, who work for their livings in England and seldom or never go abroad, ever try to keep up any language, living or dead, that they may have learned at school? Not many, I fancy!—at thirty-five, few of such Englishmen are as good linguists as they were at seventeen, and some at least have lost whatever linguistic knowledge they ever possessed.

I do not say that these men are idle or incompetent in any way—I simply say that they give up the study of foreign languages. That being so, my argument for the retention of compulsory Latin may almost be summarised as follows. Modern languages may be of great use to the student in after life—if he will keep them up. But Latin will be of use to him in his student days, and we ought to make him learn a little before entering College.

At the same time I think it quite possible that the present requirements in Latin are higher than they need be. I do not think it necessary that a student should be able to answer difficult questions in Syntax, or do much translation of "unseens." But I do think it necessary that he should know the elements of Latin to simplify what would otherwise be the intricacies of scientific nomenclature. I see no reason why, in our proposed "Special" Matriculation, the standard for Latin should not be lower than other subjects—but it ought to remain a compulsory subject.

Yours faithfully, "THREE YEARS GRADUATE"

"BISSULIN"—A CORRECTION.

Dear Sir,

In the short article I wrote you on "Bissulin," in the treatment of contagious abortion, which you published on the 28th March, there is an error in the constituents of the preparation. It should read, 0.25 per cent. of "Sozodol" Mercury, instead of 25 per cent. The latter proportion would be too strong, and would act as an irritant, which "Bissulin" is not.

Yours faithfully, E. C. WINTER, F.R.C.V.S.

Royal Counties V.M.A.

A General Meeting will be held at the Crown Hotel, Faringdon, on Friday, April 24th. The Chair will be taken by the President, Mr. J. C. Coleman, at 2.15. Agenda. Routine business. Appoint delegate to Royal Sanitary Institute Congress. Resolution by Mr. Slocock that the title of the Association be altered to "The Royal Counties' Veterinary Association" by the omission of the word Medical. Proposed formation of a Veterinary Inspectors' Branch of the R.C.V.M.A. Discussion on the "Working of the Tuberculosis Order," opened by Mr. S. H. Slocock. Review of the second Interim Report of the Departmental Committee on Swine Fever, by the Secretary (if time permits). Specimens or cases of interest. Tea will be provided at the kind invitation of Mr. J. H. Parker.

VOL. XXVI.

THE DOGS' PROTECTION BILL.

Last week a Bill designed to abolish scientific experiments upon dogs passed its second reading in the House of Commons. A memorial has been sent in against it, signed by men of the highest standing in all branches of medicine, including Sir John McFadyean and Prof. Charnock Bradley in our own department. Nevertheless, the Bill will probably become law, and in that case the progress of both human and veterinary medicine in this country will be set back. Veterinary medicine will be especially handicapped, and in one important direction it will be brought to a standstill—for this Bill will debar research into the etiology and prevention of distemper. Research work upon distemper is being done in England now, and no disease stands in greater need of research. Distemper distroys more than half the dogs that are born, and in Germany is aptly designated "the dog scourge." That all attempts either to discover its cause or to immunise dogs against it should be prohibited in England by the action of professed dog-lovers is surely one of "life's little ironies."

FOOT-AND-MOUTH DISEASE AT BIRKENHEAD.

On February 26 last three veterinary officers of our Board of Agriculture—Sir Stewart Stockman, Mr. A. M. Munro, and Mr. W. J. Young—and three of the Irish Veterinary Department—Messrs. D. S. Prentice, J. S. Norris, and J. Purdy—held an official conference at Birkenhead with regard to the outbreak of foot-and-mouth disease there earlier in the same month. The result has now appeared in the form of a somewhat unsatisfactory official report.

A complete agreement was not reached. The English representatives were agreed, and signed a report of their own. Mr. Prentice, while in agreement with the major part of this, yet differed so far in some respects that he prepared an independent report, which was also signed by his two colleagues. These two reports, with some minutes of the proceedings, make up the whole publication, and, as the minutes are incomplete and only partially verbatim, they can scarcely assist in deciding between the two conflicting opinions.

It will be remembered that on January 30th and February 1st foot-and-mouth disease was discovered at two centres in the Irish County of Kildare. The English authorities at once prohibited the landing of Irish animals otherwise than for slaughter within the landing place. Nearly a fortnight later disease began to appear at Birkenhead in animals which had landed from Ireland and were awaiting slaughter. Fourteen cargoes in all were implicated. Naturally it was inferred at first that infection had

come from Ireland, but subsequent developments cast a doubt on this view.

A quotation from the minutes summarises the problem dealt with at the Conference. "That foot-and-mouth disease has existed at Birkenhead is not disputed. All the evidence at first available pointed to the probability that the infection had been introduced by animals carried from Ireland. Since, however, no fresh disease centre has come to light in Ireland, the question has arisen as to whether it is possible that the infection can have been introduced into the lairages at Birkenhead by some other means or from some other source."

The net result of the Conference was to lessen the suspicion of infection having come from Ireland; and the real point of disagreement was the question whether any suspicion could be said to remain. The English representatives consider that "it is not possible to exclude the view that infection may have been introduced from Ireland"—but they do not affirm the view as a probability.

Mr. Prentice, on the other hand, claims that "the evidence clearly shows that the disease was not brought from Ireland to Birkenhead." It was agreed that none of the animals were found diseased upon landing; but, if they all became infected at Birkenhead, some of the periods of incubation were certainly unusually short.

Mr. Prentice explains this as arising from the debilitating effects of the journey and the virulent type of the outbreaks—for at Birkenhead the disease assumed a virulent form. Mr. Prentice emphasises two other points. The most careful search amongst animals in Ireland which had been in contact with those afterwards found affected at Birkenhead failed to unearth any disease amongst them. Further, though other animals, many from the same parts of Ireland as the Birkenhead cargoes, were shipped at the time to half-a-dozen other British ports, disease appeared at no port except Birkenhead.

Upon the whole the conference was disappointing. As an illustration of the practical complexities of animal epidemiology, the report makes really interesting reading. Incidentally, too, it elucidated a chain of circumstantial evidence which renders it almost certain that the outbreak of disease discovered at Redditch on February 22nd was due to infection at Birkenhead. But as an enquiry into how Birkenhead itself became infected, the results were absolutely negative. Perhaps a longer conference might have been more valuable, one day was a very short time to deal with the mass of complicated details that had to be considered, and further discussion might at least have produced a united report.

ABSTRACTS FROM FOREIGN JOURNALS

A NEW EQUINE VERMINOUS ENTERITIS.

Cuillé, Marotel, and Roquet have published (*Revue Gén de Méd. Vét.*) the following observation. The subject was a foal, coming from a breeding establishment which had already repeatedly lost animals from the same disease.

This foal had been brought up upon the pasture, and showed every appearance of health. Suddenly, however, he was attacked by very severe colicky pains, which lasted twenty-four hours. From that time, although the appetite was maintained, the animal fell away in condition and became so feeble that, having lain down, he was unable to rise again without help. When brought to his feet again, he neighed, played, and ate like a normal foal.

The mucous membranes were very pale, and the conjunctival slightly œdematous. The temperature was 99.5° F. The fæces were fairly well moulded, but badly digested. They contained numerous intact oat-grains and coarse *débris* of fodder. When examined microscopically, they were found to contain numerous eggs of strongylides—twenty to thirty in each preparation.

The appetite soon became capricious. An œdema then appeared, which was localised at first to the four limbs, and then extended progressively upwards. The scrotum, the sheath, and the inferior aspect of the abdomen became infiltrated in their turn, and the foal assumed the aspect of an anasarctous subject. This condition persisted for ten days; and then a profuse and fetid diarrhœa appeared, and caused death in forty-eight hours.

Post-mortem lesions were found upon the whole extent of the intestine. The mucous membrane, when freed from alimentary materials, appeared riddled by a multitude of small dark cysts of from half a millimetre to two millimetres (= 1.50 inch to 1.12 inch) in diameter. They were scattered irregularly upon the mucous membrane, and were very closely approximated together—twenty-five to thirty could be counted in a square centimetre (= 4.10 inch). The larger ones were translucent, rounded or oval in form, slightly projecting, and limited by a blackish-grey ring.

Scrapings from these cysts were found to contain larvæ of nematodes. The wall of the intestine was thick and firm, and had not changed its colour, with the exception of showing some dark red ecchymoses.

Histological examination of the cysts showed that they were situated in the interior of the mucous membrane. They were oval or polyhedral in form, and surrounded by the adenoid tissue of the mucous membrane. Their walls, which were thin, were constituted by closely packed connective tissue fibres. In the interior of the cysts the parasites could be seen, cut in all directions by the section, and the details of their structure could thus be studied. One specially notable feature of the parasites was the abundant pigmentary granulations they contained.

Embryos of the parasites were found situated in the thickness of the adenoid tissue, *without* cystic formation. Some of these embryos had crossed the muscularis mucosæ and were found in the submucous tissue. The submucous tissue was sclerosed, and infiltrated with leucocytes. The blood-vessels were chronically inflamed, which the authors attribute to the irritant action of the neighbouring parasites or of their toxins.

In the *lumen* of the intestine, numerous adult worms (*cylicostomes*) were found, together with larvæ identical with those found in the thickness of the mucous membrane. The authors explain the method of infection and the course of the disease as follows: The worms arrive in the intestine as free embryos, probably by means of impure drinking water taken in humid marshy pastures.

These embryos penetrate into the intestinal mucous membrane, where they develop, thereby causing the formation of cystic cavities. The cysts finally open into the intestine, where the parasites undergo a further metamorphosis into perfect *cylicostomes*. Copulation takes place in the intestine. The females soon lay their eggs, which are then discharged by the host with the fæces, and which, if they fall into humid surroundings, produce embryos which may, by means of water, be re-introduced into the intestines of other foals.

This observation shows the gravity and importance of a new verminous enteritis. It is especially to be noted that the principal lesions are due to the larvæ situated in the thickness of the mucous membrane, which is thus profoundly altered.

As a preventive measure, it is advisable to drain pastures which are too humid or marshy, in order to hinder the development of the embryos. The authors also recommend dressing the land with lime and sulphate of iron.—(*Annales de Méd. Vét.*)

[No details of the structure or dimensions of the parasite are given in this note].

RESEARCHES UPON CANINE TUBERCULOSIS.

Hendrik Schornagel, of Utrecht, has recently communicated his investigations upon this subject in an inaugural address at Bern. In the course of 568 post-mortem examinations of dogs carried out in the Institute of Pathological anatomy at the Utrecht Veterinary School, eleven cases of tuberculosis were found. This represents a proportion of 1.9 per cent.

The organs which were found affected, stated in the order of frequency, were the mesenteric lymphatic glands, lungs, bronchial lymphatic glands, pleura, liver, mediastinal lymphatic glands, neck, spleen, and (in one case each) the peritoneum, mesentery, pancreas, and kidneys. Generalised chronic tuberculosis was present in three cases, and generalised acute miliary tuberculosis in one case. In eight cases the tuberculosis caused either death or such severe illness that the dogs were destroyed as incurable.

The author finds that tuberculosis of the dog has no great similarity in its pathological anatomy with that of the other domestic mammals, except the cat. Histologically, also, the tuberculous nature

of the disease was difficult to recognise in most cases. Giant cells were not found in a single case, and calcification was only observed once. The diagnosis of tuberculosis was established by the discovery of tubercle bacilli and the positive results of the inoculation of guinea-pigs.

Of eight strains of tubercle bacilli which were cultivated, two belonged to the bovine type and four to the human type, while the other two represented transition forms. Consequently, a high percentage of the dogs were infected by human tubercle bacilli. A tuberculous dog therefore represents a by no means negligible danger to human health.—(*Berliner Tier. Woch.*)

W. R. C.

TENTH INTERNATIONAL VETERINARY CONGRESS, LONDON, Aug. 3—8, 1914.

I have received the following donations and payments to the Organising Fund of the Congress since you published my list dated December 27th, 1913, in *The Veterinary Record* of Jan. 3rd, 1914.

My attention has been drawn to the following errors in previous lists of donations, viz. :—

The Veterinary Record, Dec. 7th, 1912. Southern Counties V.M.S. £31 10s. promised, should read £10 10s. promised and £10 10s. paid, and Young, J., should read Young, W. J.

Nov. 29th, 1913, delete Packman, W., £5 5s., he is included in the present list and, Hodgman, J. A., should read £2 2s. paid.

Jan. 3rd, 1914, for Dunlop, D., read Dunlop, J.

I am still some £60 short of the minimum sum to be raised by the profession, and I trust that this will soon be made good. I will thank all those who have promised donations and have not yet forwarded them to kindly send them as soon as possible, and so save me the trouble of writing them personally.

FRANK W. GARNETT, Hon. Treas.

Dalegarth, Windermere.

April 7th.

Those names marked with an * denotes persons and societies other than veterinary.

CENTRAL VETERINARY SOCIETY [NATIONAL V.M.A. SOUTHERN BRANCH.]

The monthly general meeting was held at 10 Red Lion Square, W.C., on Thursday, April 2nd, Prof. G. H. Wooldridge, President, in the chair. The following Fellows signed the attendance book: Messrs. W. R. Davis, M. G. Byerley, J. F. Macdonald, H. D. Jones, J. B. Buxton, H. J. Parkin, G. H. Livesey, N. Almond, Capt. G. Rees-Mogg, S. H. Slocock, J. W. McIntosh, W. R. Clarke, R. Eaglesham, Prof. E. B. Reynolds, L. Auchterlonie, R. Bryden, J. Willett, E. L. Stroud, J. C. Coleman, F. G. Samson, W. S. King, W. Perryman, W. Willis, F. W. Willett, W. N. Thompson, G. Gordon, and Hugh A. MacCormack, hon. sec. Visitors: T. C. Toope and T. A. Huband.

On the proposition of Mr. McIntosh, seconded by Mr. Samson, the minutes of the last meeting were taken as read and confirmed.

Correspondence. The SECRETARY reported the receipt of a letter from Lieut.-Col. E. Taylor, A.V.C., regretting his inability to be present, and also announced the receipt of a circular letter from the conjoint veterinary associations (Ireland) on the subject of the direct representation of Ireland on the R.C.V.S., and asking for the support of the Society for Mr. Howard.

The PRESIDENT said it was the custom of the Society not to ask its Fellows to vote for any particular candidate but to leave the matter to the free choice of the Fellows, and therefore the letter should lie on the table.

This procedure was agreed to.

MORBID SPECIMENS.

Mr. J. WILLETT exhibited a specimen from the bowel of a dun pony that had been working in Regents Park, drawing the roller and mower and tip cart. On Feb. 4th it was brought to him in a debilitated state suffering from obstinate constipation. He found the pulse

very feeble, the mucous membrane sclerotic, and faeces in small pellets. The teeth were very ragged, and he came to the conclusion there was liver trouble. The teeth were attended to, and a purge was given, followed by stimulants; the pony began to pick up towards the end of February, and he ordered it for work again on the 28th. On March 26th the pony was down, reported unable to rise, but when seen by his assistant the animal was standing and showing symptoms of colic with no acute pain but general uneasiness. The pulse was feeble. The conjunctiva showed no inflammatory symptoms at all. Towards the evening the pain became more intense, and enemata were given without result. There was no straining, but opiates had very little effect in lessening the pain. Prognosis very unfavourable. In the morning the animal was shot, and a post-mortem was made by Mr. Jackson, who was acting as locum, and it revealed several very large patches of discoloration of the small bowel which, when opened, had enormous ulcers with green centres. The bowel was fairly full, and on cutting into it a large intussusception was found, the small bowel passing through the ileo-caecal valve about 3ft. in length, on the end of which was a tumour-like enlargement about the size of an orange. It was only in the latter part of the time that the pony sat upon its haunches like a dog. The specimen had been shown to Professor Wooldridge at the College, and also to Sir John McFadyen, who said the condition was tuberculosis of the bowel. One would have thought that with so many ulcers there would have been diarrhoea, but during the whole month the evacuations were small pellets about the size of walnuts. He had a theory that the disease might have been caused by human infection, because the animal was always eating the grass in the Park, which was the promenade of patients from a number of nursing homes in the neighbourhood, and their sputum may have been on the grass. The pony was thin, but picked up markedly towards the end of the month of February.

The PRESIDENT said the tuberculous ulcers were of enormous size, some being three inches in diameter, and there were tuberculous masses in the intestinal wall. The tumour-like enlargement at the end rather suggested in appearance a glans penis of a horse; it was the intussusception of the ileum through the ileo-caecal valve.

Mr. LIVESLEY exhibited the penis of a large fox-terrier which for the last eighteen months had been suffering from intermittent hæmorrhage from the sheath. It occurred sometimes once in a week or two, and sometimes the dog would go as long as two months. When the attack occurred blood slowly dribbled from the mouth of the sheath, and sometimes increased to a flow. Latterly the hæmorrhages had increased in severity and in number, so that the dog sometimes had as many as five in twenty-four hours. The dog would stagger about and show all signs consequent upon loss of blood, but his power of recuperation was extraordinary. For some hours before the attack the dog would be uneasy and for hours together would not lie still. On the upper side of the penis he found a small round hole, which had all the appearance of being a ruptured vein. He inquired from the owner if there was any erection to account for engorgement and consequent hæmorrhage from rupture, but during the whole time he had never seemed to have had an erection, and the penis never seemed to be enlarged. The owner was anxious to keep the dog going on as he was, provided there was no danger to his life, but some months later he complained it was becoming very difficult to manage the dog in the house owing to the blood. At this period he distinctly felt lumps in the body of the penis itself close by the small hole where the hæmorrhage arose, and it seemed to him it might possibly be a malignant growth, because the inguinal glands were enlarged. Prof. Wooldridge had offered to examine the growth under the microscope.

Mr. McINTOSH exhibited part of the right innominate bone of a van mare destroyed as a result of an injury. Fractures of the innominate bone were not uncommon in London horses, but there were some peculiarities about the present case which he regarded as unusual. Notwithstanding the extensive and complicated nature of the fracture, the lameness at the onset was very slight. He was unable to diagnose fracture for a considerable time. The animal was in foal, and two days after the lameness made its appearance, she picked her foal, and the following day was exceedingly lame, and it was only through that he was able to discover a fracture. Whether efforts to pass the foetus had anything to do with displacing the bones he could not say; he thought it probable. The fracture extended through the acetabulum in three directions. There was no history of a fall or any injury likely to bring about such a condition. Was it possible that pregnancy has anything to do with predisposing the bones to fracture?

The PRESIDENT asked in what position the affected limb was held.

Mr. McINTOSH said the limb appeared shortened, and was suspended with the toe on the ground. The mare was six years old.

The PRESIDENT did not think the pregnancy had anything to do with it. One symptom he had seen in horses where there had been a fracture involving the acetabulum was marked adduction, the affected limb being held across the front of the sound limb, sometimes resting on the ground with the tip of the toe on the opposite side of the middle line. This was constant and very marked indeed in the dog, in which animal the fracture was most frequently seen.

Mr. McINTOSH said he noticed no abduction or adduction in the present case.

The PRESIDENT said the specimen of the penis of the dog was of considerable interest, and he would try and determine what was the cause of the hæmorrhage. He did not think it would turn out to be a malignant growth. The enlarged glands might have been due to an infection of the wound. It was more likely to be due to an injury to the os penis or corpus cavernosum. When he was first spoken to about the case he suggested that a remedy might be found in preventing erection by castration *plus* large doses of bromide, until the wound healed. The suggestion, however, was not put to the test.

Mr. J. C. COLEMAN exhibited specimens of parasites found in the horse's feces, and asked whether they could be identified. Were they the *S. Tetracanthus*? For the past four years he had had a client who bred hunters and cart-horses, and at the age of three years one of them became very emaciated, with staring coat, and very weak. Although each year for the past four or five years parasitic infection of the bowels was suspected, none have been observed until this year. At present he was treating the cases with ferri sulph. and gentian; occasionally there was diarrhoea. It always attacked horses at three years old, and the present case was the fourth he had had in five years. They became worse and worse, and were ultimately sold for a small price. Last year a hunter was sold for £15 which could have been sold for £100 at two years old.

Capt. REES-MOGG showed the third cervical vertebra of a horse which fell but got up and walked home a distance of two miles. The horse lived for a week, and was able to eat all right if the food was lifted to him, but could not lower his head. A week later he fell down with symptoms of fracture and died within twelve or fourteen hours, and then a bad fracture of the vertebra was discovered.

The PRESIDENT thought the case would have done admirably well with Mr. Price's neck splint exhibited some time ago to the Society.

Prof. ALMOND said he had a case of recurrent hæmorrhage in a bull-dog, but could not pursue it as the owner moved out of the neighbourhood. The hæmorrhages existed for a considerable time, and the animal came into the infirmary on two different occasions. He did not appear to suffer much pain or much trouble.

Mr. LIVESEY said he could bear out what the President had said as to the carriage of a lame leg in a fracture of the acetabulum in the dog; the leg was held fairly straight, the toe extended, and the leg adducted, and carried in front of the sound foot.

Mr. MACDONALD said that in the Dick Veterinary College there was a specimen of innominate bone similar to that shown. The case recovered and the animal worked for several years.

Mr. DAVIES suggested that Mr. Coleman should try plenty of milk for his case. He had found milk and cod-liver oil very good in such cases on farms in Cambridgeshire, where the disease is extremely rife. The ordinary anthelmintics, including Thymol he had found without effect.

Prof. ALMOND said there was no doubt about the identity of the parasite; it was a *sclerostoma tetracanthum*. He had recently had a case in a four-year-old mare in which the parasite was first observed about July, and she continued to pass parasites for about twelve months. They were not all of the red colour shown by Mr. Coleman, the greater number being quite white.

Mr. COLEMAN said everyone of the parasites in his case was red.

Prof. ALMOND said that if put into water the red colour generally disappeared. While he was away on a visit the animal was treated by another practitioner with carbolic acid, half an ounce in a pint of linseed oil, but that set up a great deal of pain. On his return he put the mare on carbonate of iron, and encouraged her to eat. She was kept warm, and given about two drams of carbonate of iron every night and morning with her food, and was now quite well.

Mr. HUBAND said Mr. MacIntosh's specimen was an exceedingly interesting one as showing the amount of fracture which might occur without seriously affecting the animal before displacement. He had seen many cases of fracture of different portions of the innominate bone with evidence of recovery. With regard to the fracture of the cervical vertebra, it reminded him of a horse which ran away and came in contact with a stone pillar. He was called to the horse as it lay in the road, but could not make out much the matter except that it was stunned. He sent along a harmless draught by the yardman and raising the head to give the draught, displacement occurred, and the animal gave a few kicks and died. The crowd naturally thought the draught had killed the horse and began to laugh, but the yardman turned round and said: "You need not laugh, that is just what Mr. Huband said, if it does not cure him it will kill him."

Mr. PERRYMAN said in all cases of fracture there was constant hæmorrhage between the fracture, and a gradual widening of the broken portions of the bone by the blood clot. That was exemplified very often in pelvic injury. In many cases it was impossible in the first stages to diagnose definitely where the fracture was, and he thought the same thing applied to the cervical vertebrae. He had known cases of pelvic injury last a few weeks without any displacement until a sudden wrench separated the bones. He had a case last year in which the bone was broken from the symphysis into the acetabulum, and the animal held the leg forward and pivoted round on the other leg. In milder cases, where the acetabulum was not much involved, it was possible to have recovery.

The PRESIDENT said the parasites shown by Mr. Coleman appeared to be *Sclerostoma tetracanthum* and the symptoms described were quite commonly met with, causing in most instances suspicion of tuberculosis. Treatment was not always successful even under the best circumstances. Horses would recover without any treatment, while others would gradually get worse and die under any method of treatment. The cause of death appeared to be due to a secretion by the parasites causing hæmolysis, and death was due to exhaustion. If a horse was not already up from pasture he should be got up and given a supply of concentrated highly nutritious foods, rather on the dry side than laxative, and after he had begun to eat his food he should be given such vermicides as Arsenic, Antim., Pot. tart., and Sulphate of iron. Thymol was strongly recommended by some practitioners. He had been told by a country practitioner that by some mischance a case of his was given half a pint of petroleum oil, such as was used for lighting, and the horse began to improve materially. On a number of subsequent occasions he had repeated the line of treatment and had had better success from that than from any other. The chief difficulty in the disease was the fact that the worms were in the large intestines and frequently buried in the wall, and therefore almost beyond the reach of medicines before they were excessively diluted. A half-pint of petroleum given after fasting seemed rather a drastic method, but it should be remembered that the fluid would run straight away through into the cæcum, and would affect the worms more directly than any other line of treatment.

Mr. HUBAND said he had known cases of parasitic infection where the regular employment of rock salt had had a marvellously good effect in improving the conditions.

Mr. COLEMAN said the owner of the horses was a great believer in rock salt, and kept it in all the fields. The horse had shown no decline in condition.

Mr. TOOPE said many years ago he had a horse constantly suffering from flatulent colic, and on one occasion it was so enormously distended that he punctured the intestines with a small trochar and injected a considerable quantity of antiseptic fluid, terebene. To his astonishment the following morning the excreta was practically full of worms, and he came to the conclusion that terebene was the most effective vermifuge he had ever seen given in that way. They were all round worms, strongyles, of various descriptions. On other occasions he adopted the same line of treatment, but not with the same success.

Mr. SLOCOCK believed it was acknowledged that the *tetracanthus* existed for many years in a brood mare, and once she had it she had it for a lifetime.

Mr. COLEMAN said the mares were all different; one was a hunter, and three were colts. One of them was bought and not bred on the place.

The PRESIDENT thought there was no doubt the infection came from the land.

Election of Fellow.—Mr. JOHN BROWNLESS, M.R.C.V.S., of Kensington, was unanimously elected a Fellow.

Royal Sanitary Institute Congress. On the motion of Mr. J. Willett, seconded by Mr. E. Lionel Stroud, the President was nominated as delegate to the R.S.I. Congress at Blackpool, from July 6th to 11th.

Election to Council of National Veterinary Medical Association.—The PRESIDENT said the Society was entitled to six representatives on the Council of the National V.M.A.

Prof. ALMOND proposed that the present representatives should be re-elected:—Messrs. McIntosh, Foreman, Slocock, Davis, J. Willett, and Prof. Macqueen.

Mr. COLEMAN seconded the motion, which was carried unanimously.

ON THE INFLUENCE OF AN INJECTION OF MALLEIN ON THE SERUM DIAGNOSIS OF GLANDERS.

By J. BASIL BUXTON, F.R.C.V.S., D.V.H.

(This appeared in our issue of April 11th.)

Before reading his paper Mr. Buxton explained that when any foreign organisms were introduced into an animal various antibodies were produced, some of great importance and others not so important. Agglutinating antibodies were perhaps some of the most important and had the peculiar property of linking up with some substance or substances in the bacterial cells and so causing clumping of those organisms.

The complement binding antibodies were probably of the nature of bacteriolysins, at any rate they possessed a similar composition. Bacteriolysins were composed of two essential parts, an amboceptor and complement.

The amboceptor, as its name implied, was a link, and possessed the power of joining up on one hand with the antigen, in this case the specific bacterial cells themselves, and on the other with the complement, and while the complement had little or no affinity for the specific antigen it had a very marked affinity for the amboceptor. Similarly while the amboceptor was able to link up with the antigen bacteriolysis did not occur except in the presence of complement. When such a union took place, namely complement, amboceptor, and antigen, bacteriolysis occurred. While the amboceptor was a thermostable body, *i.e.* resisted heating for 1 hour at 55° C., the complement was destroyed under similar conditions, and in the complement fixation test advantage was taken of this fact. The natural complement which existed in an unknown amount in the specific serum to be treated was destroyed, and replaced by a known amount of complement of known strength. The amount of amboceptor contained in the specific immune serum which was required to complete the system, *i.e.* link up with the known amount of complement and antigen, was spoken of as the complement binding titre of that serum.

DISCUSSION.

Prof. ALMOND, while thanking Mr. Buxton for his paper, confessed it was beyond his ability to criticise it. He had some knowledge from current literature of the various bodies produced in the animal economy, and there was no doubt that they were of the very greatest possible interest to those who were able to follow them and utilise them, but they appeared to be beyond the ability of the ordinary practitioner. It seemed to require a well appointed laboratory to be able to test the influence of the method, and evidently it was not intended for employment by ordinary practitioners; it did, however, show the direction in which medical research was going, and as such was of extreme interest.

Mr. PERRYMAN asked whether the injection of mallein had any effect on the toxins of other diseases, such as the pneumococcus and streptococcus—any retarding action in the development of them. Would an injection of mallein into an animal suffering from strangles or pneumonia reduce the temperature? On more than one occasion he had injected an animal having a high temperature with a dose of mallein, and he found the temperature came down in a remarkable manner. In testing a stud for glanders it was remarkable to see how some aged and debilitated animals would begin to pick up after an injection. This was the experience of many veterinary surgeons he believed. Also he wished to know whether the injection of mallein was curative in the case of an animal already affected, and preventive when injected into an animal not affected.

Mr. DAVIS said he had gathered from *The Veterinary Record* that there was an opinion abroad that not much reliability was to be placed on the use of mallein as a diagnostic agent in the detection of glanders. He had used a good many thousand doses himself, and had come to the conclusion years ago that a great deal depended on the quality of the mallein. During the South African war every animal, horses and mules, had to be tested, and with some of the American malleins the usual reaction did not take place, but there was the formation of a doughy swelling, often developing later into a necrotic mass. He was quite satisfied that proper mallein was as absolutely certain in diagnosing glanders as tuberculin was in diagnosing tuberculosis. With regard to mallein reducing temperature, at one time he had great faith in a certain remedy for the reduction of temperature, antifebrin. He had a contract for attending tramway horses, and in passing the stables one night he was asked by the Manager to look at a horse, and found it had a temperature of near 107°. The Manager, however, did not wish him to worry about it that night, and when he went in the morning he found the temperature reduced to 101°. If he had given the animal antifebrin on the previous night he should have been under the impression that it had brought down the temperature. He suggested to Mr. Perryman that if he had given an injection of *aqua pura* he might have found the temperature down in the morning just the same.

Mr. PERRYMAN said he referred to cases of persistent high temperature, when an animal had had a temperature for a fortnight. He had at present a case where the temperature had been up ten days, and he could not get it down nor find complications to account for it. He should probably give that animal a dose.

The PRESIDENT said Mr. Perryman might let the Society know the result at the next meeting.

Prof. ALMOND asked Mr. Davis at what period the necrotic masses occurred as the result of an injection of so-called mallein.

Mr. DAVIS said several days after inoculation. There was a swelling on the next day, but it became necrotic after several days.

Prof. ALMOND asked whether the swelling showed the ordinary characteristics that followed the injection of mallein in an unaffected horse.

Mr. DAVIS said no. With the mallein obtained from the Royal College afterwards no such cases occurred.

Mr. MCINTOSH said he had used many thousand doses of mallein, and he agreed with Mr. Perryman that it was capable of reducing a persistent high temperature. Another remarkable fact was that a horse which had been previously unthrifty, when dosed with mallein suddenly improved in condition and began to thrive. Apparently it altered the condition of the blood, or in some other way helped the animal to build itself up.

Mr. J. WILLETT also agreed that mallein reduced temperature. Some fifteen years ago he had a stud of 80 brewery horses which were submitted to the mallein test, and 22 of them reacted. A Professor from the College suggested that mallein was a curative, and the animals were put into a stable by themselves and had to work together, and he had to test them regularly each month over a considerable period. There were several unthrifty horses amongst them, and after several doses they began to improve in condition, and out of 18, only five were killed, and the others put back into stock again.

The PRESIDENT said there were certain practical points in connection with Mr. Buxton's paper which did not appear to have come home to most of the members. They were mainly bound up with the fact that although practitioners liked to consider mallein as near perfection as possible they could not blind themselves to the fact that it was not perfection and not always applicable; it

was a very useful agent, and the number of fallacies met with in connection with its use were fortunately comparatively few. But the limitations of the substance had been recognised on the Continent to a greater extent than in this country, so much so that in some foreign countries, Hungary in particular, diagnosis was limited to the agglutination test, which had been found to be fraught with fewer fallacies than the mallein test, and the use of mallein as a diagnostic agent had been made illegal because it interferes with the agglutination test.

So far as he was aware there had not been sufficient attention drawn to the comparative advantages of the complement fixation test and the agglutination test previously, and Mr. Buxton's work might assist materially in that direction, because if Mr. Buxton's work was supported by other investigators the necessity for rendering the use of mallein illegal would no longer operate, for instead of putting the horse through the agglutination test, the complement test could be applied in cases of doubtful results from the mallein test. The mallein test was the easiest to apply, and the most satisfactory to the practitioner, as he could carry it through without having to send it to a laboratory. An interesting feature mentioned in the paper was that the blood again returned to normal in from four to five weeks after an injection of mallein, so that the agglutination test could be applied after that time. That, however, was a long time in connection with an outbreak of glanders. He would like to know if Mr. Buxton's horses were all being used for the production of various immune sera, for although it was regarded that the antibodies were absolutely specific, yet he thought a good deal remained to be done in that connection, and that had been generally pretty clearly shown in Mr. Buxton's own results.

Was it definitely proved beyond any dispute that the process of immunising animals against other organisms did not interfere in any way with the production of antibodies when mallein was injected? In Mr. Buxton's cases the production of antibodies causing agglutination was fairly constant, yet there were two specific cases where antibodies were produced, and the complement fixation test was interfered with. One, he believed, was the gonococcus, and the other the meningococcus. These were two cases where horses being immunised against two sets of organisms had the reaction interfered with, and he should like to know whether it was beyond all doubt that such a thing might not occur in other instances. He did not think many practitioners used mallein as a febrifuge, and he did not think they intended to. In some cases which he had suspected of being affected with glanders and had submitted to the test, although he had had no reaction either in temperature or local swelling, the horses that had been previously off their feed and unthrifty had suddenly taken to eating well and had begun to thrive. He remembered calling Mr. Hunting's attention to similar cases and asking his opinion, but all he could get from him was a shake of the head and, "I should regard such cases as suspicious and test again." That was a very sound dictum. He hoped Mr. Buxton would proceed with his work and bring it to still further fruition.

REPLY.

Mr. BUXTON, in reply, said he had hoped that some of the members would have come across cases suspected of being glanders in which they had obtained no reaction to mallein, and where they possibly had had the agglutination test carried out subsequent to the mallein test. He did not know that mallein could be used as a febrifuge, but apparently it had produced some very startling results. With regard to Prof. Wooldridge's remarks, no one had ever suggested that an animal possessing antibodies produced by other organisms

would not give to some extent reactions to the bacillus mallei, and that was borne out in the case of two instances he had quoted, the horse that was being injected with dead meningococcus and the horse injected with dead gonococcus. In some cases of young horses which had recently recovered from an infection with *Streptococcus equi*, he frequently found they got a typical reaction to mallein if tested within a week or two of their recovery. What was more disconcerting, such horses would give a comparatively high agglutinating titre, so that one was not able to say whether the horse was free from glanders or not. Fortunately, however, the complement fixation test furnished a much more definite knowledge. Some cases were on record in which the body cells had been sensitised by streptococcus equi, and the result of the mallein test had been a local swelling, sometimes accompanied by a rise of temperature, but the swelling had not followed the course generally observed in a glandered animal. With regard to the horses being immunised, he would point out these were used more or less as controls. Of

the 29 horses he had recorded every horse was normal. With reference to the question of the curative effects of mallein and the prophylactic effects, one would have every reason to suppose that were mallein given in sufficiently large doses it might possibly exert some curative or prophylactic effect. He did not mean to suggest that 5 or even 10 c.c. was going to have a prophylactic effect, as the doses would have to be much larger and given over a fairly long period.

On the proposition of Mr. Samson, seconded by Mr. E. Lionel Stroud, a hearty vote of thanks was accorded to the gentlemen who had brought forward post-mortem specimens.

A hearty vote of thanks was also accorded to Mr. Buxton, on the motion of Mr. J. Willett, seconded by Mr. Davis.

The meeting then adjourned.

* As Diseased or Exposed to Infection

SOUTHERN COUNTIES VETERINARY SOCIETY.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The thirty-third annual general meeting was held at the Royal College of Veterinary Surgeons, Red Lion Square, London, on Thursday, the 26th March, when the retiring President, Mr. G. H. Livesey, of Hove, took the chair, and the others who signed the attendance book included Professor G. H. Wooldridge, London; and Messrs. J. T. Angwin, Arundel; A. H. Archer, Southsea; Walter Burt, junr., Brighton; Gerald W. Bloxsome, Hove; E. Whitley Baker, Wimborne; F. G. Samson, Mitcham; and P. J. Simpson, Maidenhead; together with Mr. J. Basil Buxton, and Mr. H. A. MacCormack, London.

Apologies and expressions of regret at inability to attend were announced from Messrs. P. Carter, W. Coveney, E. R. Harding, H. Leeney, J. B. Martin, J. C. Mumby, A. H. Lockwood, C. Pack, C. H. Spurgeon, H. Smith, R. A. Thrall, J. Alex. Todd, D. Wyllie, and F. T. Walder.

On the proposition of Mr. P. J. Simpson, seconded by Mr. Angwin, the minutes of the last meeting as published in *The Veterinary Record* were taken as read

and confirmed, and on the motion of Mr. Walter Burt, seconded by Mr. Bloxsome, the rules of the Society were also taken as read.

The HON. SEC. (Mr. A. H. Archer) submitted a communication from Mr. J. H. Carter, the President of the Royal College, enclosing a form of petition to the Treasury for a civil pension for the children of the late Mr. William Hunting.

The PRESIDENT, after the text of this petition had been read to the members, remarked that he would move from the chair that it be signed by himself on behalf of the Society. Prof. Wooldridge seconded, and the meeting agreed.

Mr. E. WHITLEY BAKER remarked that while they were on this subject he should like to move as Treasurer that they should also vote the sum of £5 5s. from their funds to the Hunting Memorial Fund. When they remembered what the late Mr. Hunting did for the profession, and for their own Society in particular, he thought it would be a graceful and fitting act for them to make some little grant to that Fund.

Mr. BURT: Have you any idea what form this memorial is likely to take.

Mr. BAKER replied that he had been given to understand that the money, or at all events the greater part of it, would be invested on behalf of the family.

Mr. ANGWIN seconded, and the proposition to vote the five guineas was unanimously agreed to.

Prof. WOOLDRIDGE, replying to a question by Mr. Samson, explained that no definite steps could be taken until it was ascertained approximately how much money would be collected, but there was no intention of devoting the whole of the money to a stone memorial.

Mr. BLOXSOME asked when the fund was likely to be closed.

Prof. WOOLDRIDGE replied that it would certainly not be closed until they saw whether this petition for a pension was granted. The allocation of the fund would also depend very largely on whether they succeeded in getting a pension or not, because if the pension was obtained the capital, or the bulk of it, might be invested for the benefit of the family and then to revert to the Royal College of Veterinary Surgeons. Nothing definite had, however, been decided yet.

Mr. BLOXSOME remarked that personally he had a great objection to subscribing to permanent memorials that were going to take the form of a piece of stone, and he believed many other members of their profession had the same objection, but if they knew that their money was going to serve some useful purpose he believed there were many who would only be too pleased to subscribe.

The PRESIDENT remarked that he personally had refrained from subscribing until he knew what form the memorial was to take, because if it was going to take the form of a stone, or some small scholarship, he confessed he should not subscribe very heartily, much as he esteemed the late Mr. Hunting, but if the money was going to be spent for the welfare of the family he would gladly give, and he was sure many others would as well.

Mr. SIMPSON asked if they could not embody this opinion in their resolution.

Mr. BLOXSOME: I am afraid it would be rather difficult to do that, but in sending the money we could express the hope that it will be utilised for the benefit of the family.

Mr. E. WHITLEY BAKER remarked that he was quite at one with the suggestion. Personally he was as much opposed as any of them to wasting money in eulogising the dead in such a form as the erection of some monument, but he certainly felt that they ought in consideration of what the late Mr. Hunting did for their Society, to vote something, and if they authorised him to do so he would forward the cheque with a stipulation that it should not be put to any other use than for the benefit of the family.

The PRESIDENT: I am afraid, gentlemen, we have already voted the money, and if you want to make any condition I must ask for another resolution.

Mr. SIMPSON: I will move that in sending the cheque the Treasurer be instructed to write saying that it is the wish of our Society that the money shall be used preferably for the benefit of the family and not for a permanent memorial. Mr. Angwin seconded, and it was unanimously agreed to.

The HON. SEC. mentioned that he had received another letter from Mr. Garnett asking for further contributions towards the International Veterinary Congress Fund.

The PRESIDENT: You will probably remember that our Treasurer was authorised to send them a first contribution of ten guineas, I believe, and that has been done.

Prof. WOOLDRIDGE: I take it that this letter refers more to private contributions.

The PRESIDENT: Very likely, but I thought you ought to know what we have done as a Society.

Mr. E. WHITLEY BAKER thought he ought to mention the fact that he had had an application for a further donation from the Society, and on referring to the

minutes he found that when they voted the ten guineas the remark was made that if in the future they were able, they might send them a further donation. He should therefore like the feeling of that meeting as to what they wished him to do, but perhaps they would like first to hear his financial statement. [Agreed].

The next business was to consider the advisability of appointing a delegate to the annual Congress of the Royal Sanitary Institute at Blackpool this summer.

Mr. ANGWIN in view of the other demands which they appeared to have on their funds thought they could spend their money to much better advantage in other ways, and he therefore proposed that they do not appoint a delegate. Mr. W. Burt seconded.

Prof. WOOLDRIDGE remarked that there was a lot to be said from Mr. Angwin's point of view, no doubt, but there was also a good deal to be said on the other side. It was said that they could get the reports even if they did not send delegates, but if every Society adopted that course there would be no reports to receive. Seeing that there was likely to be a considerable demand on the funds of the Society, however, he would suggest that this matter also stand over until they had the Treasurer's report.

Mr. SIMPSON proposed that this be done, and this was seconded by Mr. Samson, and carried.

SECRETARY'S REPORT.

During the past year, in addition to the annual meeting last March, three meetings have been held, at Portsmouth, Brighton and London. The attendances at these meetings has been fourteen, nine, thirteen, and eleven respectively. With the exception of the last meeting, which was held in Cattle Show week in London, these numbers are about up to the average. At the latter meeting, which was followed by the customary dinner, exclusive of the veterinary inspectors who were specially invited to attend in order to form an Inspectors Branch of the Society, only seven members attended the business meeting, and six the dinner. The Society's tooth instruments have been much appreciated, as shown by their requisition on several occasions, and they are now in my possession at Southsea. There are now about seventy-eight names appearing on our list as members, but I am bound to say that some of these should, in my opinion, be no longer regarded as members. Five new members have been elected during the year, but on the other hand several have fallen out or resigned. Mr. Todd, our late hon. secretary, formally resigned on September 25th, at which time I took over the duties of hon. sec. During the past year the Society has suffered a great loss by the death of two of our most esteemed members. Needless to say I refer to the late Mr. R. Roberts and the late Mr. W. Hunting. An important feature of the past year's proceedings has been the efforts made to establish an Inspectors branch of this Society, and from which some good financially should arise, especially in connection with the fees for the examination and inspection of stock, and attendances at markets, etc.

On the proposition of Prof. Wooldridge, seconded by Mr. Angwin, the report was adopted.

TREASURER'S STATEMENT.

Mr. E. WHITLEY BAKER, in submitting his statement, remarked that their income had been £29 3s. 6d., and their expenditure £25 11s. 9½d., leaving them with an increased balance of £21 17s. 7d. He wanted to point out to them, however, that their expenditure was now exceeding their income. During the past year they had received £29, but in the previous year they only had £13 come in. Since he got out his balance-sheet he had received a further two guineas, but they had that day voted five guineas towards the Hunting Memorial Fund, and he had outstanding liabilities amounting to about

£6, the latter including £3 for their subscription to the National. I mention these facts to show you that it will be necessary for us to husband our resources very carefully in future.

Mr. ANGWIN proposed that the balance-sheet, as presented, be passed, and this was seconded by Mr. W. Burt, and agreed to.

Mr. SIMPSON asked if the accounts could be printed and sent out with the agenda another year.

Mr. BAKER replied that he would bear that suggestion in mind.

The PRESIDENT next asked for the views of the members as to making a further donation to the International Veterinary Congress Fund, adding that at the present time it was a question whether their finances warranted them in sending anything more.

Mr. BLOXSOME proposed that they make no further contribution as a Society, and this was agreed to, the President pointing out that there was nothing to prevent members subscribing privately if they choose.

ROYAL SANITARY INSTITUTE CONGRESS.

The question of sending a delegate to the Sanitary Institute Congress was next dealt with.

Mr. ANGWIN proposed that they subscribe a guinea as usual, but that unless there was some member who would be able to attend at his own expense they do not go to the expense of sending any delegate.

Prof. WOOLDRIDGE seconded this, and the same was carried.

Mr. SIMPSON hoped some one would come forward and attend the Congress, as he happened to know that these meetings did afford veterinary surgeons a splendid opportunity to make their influence felt for the benefit of the profession with a certain class of people who were in some cases rather opposed to them. At the last Congress at Exeter the best attended meetings and the best discussions took place in connection with the Veterinary Section, and although it might not come back to them individually they were doing the profession, and indirectly themselves, a great deal of good by attending such gatherings as these.

Mr. ARCHER endorsed all that Mr. Simpson had said as to the value of having delegates at these Congresses.

Prof. WOOLDRIDGE also expressed the hope that they would be able to persuade some one to attend and represent the Society.

At a subsequent stage of the proceedings the President incidentally raised the question of the amount of the allowance that had been claimed by Mr. Archer, their delegate, last year, and

Mr. ARCHER explained that although it was quite true he would have attended the Congress at Exeter in any case, as he was reading a paper there, he accepted the position of delegate on the understanding that it was on the same terms as the year before, when four guineas were kindly voted towards his expenses, and he believed he made the remark that he would be pleased to represent them "on the same conditions as last year." He would also be pleased to attend the coming conference at Blackpool as delegate for the Society if they liked, and in that case he would leave it to the Society as to whether they paid him anything or not. These conditions were agreed to.

The PRESIDENT brought forward the matter of the Reception Fund for the International Veterinary Congress. They had voted ten guineas to this Fund, and he understood when he took the chair twelve months ago that the President and Secretary of each Society had been appointed members of the general Organising Committee of the Congress. He could only say, however, that since he had been in the chair he had not received a single notice from the Secretary of any meeting, but on the other hand he had received three begging letters asking him for a subscription. It did not

seem to him that this was treating the Society with very much courtesy, and seeing that they had gone to the extent of subscribing ten guineas to the funds he thought the least they could have had in return was some little voice on the Committee. He did not know whether Mr. Archer, as Secretary, had received invitations to attend any meetings. To him, personally, it did not matter, but as President of the Society he thought the least they could have done was to have sent a notice.

Then, again, with regard to the Congress itself, it seemed to him that they were hardly treating the profession with the courtesy it deserved, in that although they had repeatedly asked for subscriptions they had not as yet told them what was going to be done. From what he had heard there seemed to be an opinion in many quarters that this Congress was being run by a certain number of people who were interested in such things, rather than for the benefit of the profession. It was a pity such an impression should have got abroad, and he thought it was due to the fact that they had not taken the Societies sufficiently into their confidence.

Prof. WOOLDRIDGE asked whether the fact that Mr. Livesey was elected their President had been officially notified to the Secretary.

The PRESIDENT: I don't know about that, but I know the changes were notified in *The Record* at the time, and that the necessary corrections have since been made in the list of the Societies and their officers which are published in the professional papers every month.

Mr. ARCHER: I can only say that I have received one invitation to any meeting, and that was forwarded on to me by Mr. Todd, and reached me too late for me to attend if I had wanted to. It was also a personal invitation to myself as Secretary.

Prof. WOOLDRIDGE: That rather seems to suggest that they have not been notified of the change in our officers.

ELECTION OF OFFICERS.

Mr. ANGWIN desired to propose the re-election of their present President, Mr. Livesey. (Hear, hear.) He had had a very broken year of office so far, owing to the change of their secretaries, and he was sure he would do still better during the coming year than he had done hitherto, and that it would be the wish of them all that he would consent to take on the office for another year. (Hear, hear.)

Mr. W. BURT seconded, and the proposition was at once put and carried by acclamation.

The PRESIDENT, in acknowledging the compliment, thanked them very much indeed for the honour they had again conferred upon him. He had no idea they were going to ask him to stand for a second year, but he should be very glad to take it on if he could in any way help on the Society. He hoped they would have a more successful and prosperous year than they had had last, and if he could do anything to that end he should be only too pleased. He thought they would be able to get some good papers, because that was what they wanted—short papers and demonstrations that would interest everybody. He could only repeat that he would do all he could to help forward the interests of the Society, and that he again thanked them for electing him once more to the chair. (Applause.)

Vice-Presidents. On the proposition of the President, seconded by Prof. Wooldridge, Mr. F. G. SAMSON was elected a Vice-president in the place of the late Mr. William Hunting, and the other three Vice-presidents, Mr. C. ROBERTS, Mr. S. H. SLOCOCK, and Mr. ANGWIN, were re-appointed on the proposition of Mr. Caudwell, seconded by Prof. Wooldridge.

Committee. Messrs. J. B. DIER, C. PACK, R. WALL, and J. T. ANGWIN were also chosen as the Executive

Committee for the coming year on the motion of Mr. Burt, seconded by Mr. Simpson.

Hon. Treas.: Hon. Sec. Mr. Angwin next proposed the re-election of Mr. E. WHITLEY BAKER as hon. treasurer, and Mr. A. H. ARCHER, as hon. secretary, and this was seconded by Mr. Simpson, and also carried unanimously.

Nomination. Mr. H. A. McCORMACK was nominated for membership by the President, seconded by Mr. Angwin.

Next Meeting. It was also decided on the proposition of Mr. Angwin, seconded by Mr. Samson, that the next meeting be held at Worthing on the last Wednesday in June.

SOME REMARKS CONCERNING THE ETIOLOGY OF CAT INFLUENZA, WITH MICROSCOPICAL DEMONSTRATIONS.

By J. BASIL BUXTON, Wellcome Physiological Research Laboratories, London.

At a recent meeting of veterinary surgeons your President was kind enough to ask me to say a few words concerning the etiology of cat influenza. At that time I did not contemplate publishing anything concerning my work in that direction, but since that meeting circumstances arose which suggested that an early publication in the form of a preliminary report was advisable. The remarks which I made have probably been seen by most of you in *The Veterinary Record*, and while I do not feel at present in a position to add to them to any considerable extent, a brief résumé at this junction may not be out of place. There seems to be a good deal of conflicting opinion in so far as my clinical observations were concerned, for while I have been the grateful recipient of a number of letters from practitioners whose daily work brings them in contact with an ever increasing number of cases resembling the disease under discussion, and who agree with the clinical diagnosis *in toto*, several eminent clinicians apparently do not recognise such a complaint at cat influenza. That there should be this difference of opinion is of advantage from the point of view of this meeting, since it should tend to produce a lively discussion on the subject which is invaluable both to you and to me. It is, however, after all quite immaterial what name one may choose to give the complaint, since I simply drew a mental picture of the chain of symptoms and make reference to an organism which I believe to be intimately associated with the causation of those symptoms. The incubation period of the disease is apparently from about ten days to a fortnight in the case of a natural infection, while in experimental animals it may be somewhat shorter. The symptoms may be presented either as a simple nasal and conjunctival catarrh in which the most obvious feature is a periodic sneezing, accompanied by photophobia and excessive lachrymation, without, at this stage, any discharge, to terminate in the case of resistant animals in resolution, or in those whose defences are not so good to be followed by a muco-purulent discharge from the eyes and nose, and an extension of the infection resulting in a pharyngitis and laryngitis. This state of affairs may persist for several days to terminate in the recovery of the animal if its strength can meanwhile be maintained, or the infection may extend, involve the pulmonary parenchyma, and cause the death of the patient from an acute croupous pneumonia. In those cases in which the third and most fatal phase is seen, the two previously mentioned stages are invariably its precursors. In a few cases the disease has been seen to run an extremely rapid course, embracing all three phases, and death has resulted in from four to five days of the on-

set of the symptoms. Such rapidly fatal cases are, however, not common, and I have only seen them in kittens of the more delicate breeds. In all stages of the disease food of any kind is refused, and the utmost difficulty is experienced in maintaining the animal's strength. As I have said before, it is very uncommon to find animals suffering from this disease affected with diarrhoea; on the contrary, there is a marked tendency towards constipation. On post-mortem examination the lesions are found to be confined to the respiratory tract. There is marked inflammation of the pharynx, larynx, and trachea, and when the lungs are affected there is a typical croupous pneumonia. I was able to isolate the organism under discussion in pure culture from the smaller bronchi, and sometimes from the trachea in almost every case in which the disease was seen in its early stages. In the pneumonia cases I was invariably able to recover the organism from the lungs, and in advanced cases from the heart blood. The agglutinating and complement building titres of the blood of affected animals has, so far as I have been able to ascertain, always been much higher than that of the blood of apparently normal controls, but much work remains to be done in that connection. As I stated in my preliminary report, the organism is a short bacillus varying in length from 1.5mm. to 2.5mm. by about 3mm. in breadth. It does not show progressive motility, is an aerobe, and does not stain by Gram's method. On many solid media old cultures show a yellow colouration, most marked at the edges and gradually extending towards the centre. In the sugar media (lactose, glucose, maltose, saccharose, raffinose, arabinose, mannite, dulcitol, adonite, dextrin, leavulose, and galactose), a slight alkalinity is produced in 24 hours at 37 centigrade, and in 48 hours there is a marked alkaline reaction. It has been found possible to transmit the disease experimentally to healthy cats, even by an injection into the nostrils of a saline suspension of the organism.

I have here an agglutination test, and a complement fixation test put up with the blood of a cat suffering from influenza, and from a normal control.

The agglutinating titre of the diseased cat is in this case 1 in 400, while that of the control is 1 in 20.

The complement fixation titre is '02, while that of the healthy cat is *nil*.

I have also some slides of the organism under discussion. One is stained with Kühne's blue, one with Loeffler's blue, and one with dilute fuchsin.

I had hoped to be able to show you a kitten suffering from this disease, but it unfortunately developed pneumonia yesterday, and died this morning.

DISCUSSION.

The PRESIDENT: Before we open the discussion, I should like to ask you if you have ever compared this with cat distemper, and have you ever found this organism in cat distemper.

Mr. BUXTON replied that he did some work relating to cat distemper some time back, but was not able to come to a satisfactory conclusion. Circumstances compelled him to leave it over for a while, but he might say that in cases of cat distemper he had not found this organism. He could also say it was not an ordinary inhabitant of the respiratory passages of the cat.

Prof. WOOLDRIDGE, who was then invited by the President to open the discussion, remarked that he had been very interested indeed to hear Mr. Buxton's description of this condition and his investigations concerning it, but he must admit that in some respects he still had misgivings. In the first place he seemed to have started with the preconceived notion that there was a cat influenza as distinct from feline distemper. Personally, although he had had pass through his hands a large number of cats affected with a catarrhal fever

which might take various forms and manifestations, he had never yet been able to satisfy himself that clinically they could be differentiated into these two separate and distinct diseases. Mr. Buxton told them that this organism which appeared to have some definite connection with the disease in question could not be found in cases of cat distemper, but he should like to know how many true cases of feline distemper he had been able to examine, since it seemed to him from the remarks he had made the investigations he had made in connection with cat distemper were concluded before he undertook this present work. At all events he gathered that the work had not been going on simultaneously, and the comparisons did not appear to have been easily made except from memory. For his own part he was not convinced that it was a separate or distinct disease. He thought the better plan would be to call it contagious catarrhal fever in the cat. If this did prove to be a separate and distinct disease and this organism should be proved to be the cause, then he said they were on the high road to some still more important discoveries in regard to preventive inoculations or curative serums. He should also like to hear Mr. Buxton's views with regard to the possibility of the transmission of this disease. He thought there were some forms of catarrh that cause temporary inconvenience in the human subject for instance, but which did not cause the pronounced nasal catarrh they got in the human being. He desired to congratulate Mr. Buxton very heartily on the valuable work he was doing in this direction, and he hoped he would be able to show them definitely by experiments and clinical investigation that there were two distinct diseases, that he had got the means of differentiating them, and that he would be able to show them how they could clinically distinguish them, but in the meantime he was not prepared to admit that there were two diseases.

Mr. ANGWIN, called upon by the President, did not think he had much to say on this subject of cat distemper, except that he had listened to the remarks of the essayist with great interest, and had been delighted with the specimens he had shown them that afternoon; and he only hoped that at some future date they might be able to hear more of the subject. He also hoped his theory would turn out to be correct, and that he would be able to make some practical use of his investigations, and give them some vaccine or treatment which would prove a perfect cure for the violent nasal discharge they got in these cases.

Mr. BURT would like Mr. Buxton to tell them what difference there was in the clinical symptoms of cat distemper and cat influenza, because he had seen a large number of cats at different times, and he had never been able to say whether they had distemper or influenza. If the symptoms they had heard that afternoon were not those of cat distemper then he did not know what cat distemper was.

Mr. SIMPSON had never been able to thoroughly differentiate clinically between the different forms of catarrh in the cat, and he could only re-echo the hope that they would get a cure for these troubles.

Mr. CAUDWELL thought distemper, influenza and diphtheria were all very much alike, and with regard to the transmission of the diseases he had never known a human being take it from the cat. It might be that they did, but he had never known of such a case.

Mr. MACCORMACK on being asked by the President for his views, observed that he desired first to thank Mr. Buxton for his short but very able paper. Continuing, he was going to take an opposite view to several of the gentlemen who had spoken—he did think there were two diseases, and that cats suffered from influenza and distemper. They might ask immediately what were the symptoms. He was not going to give them that afternoon. It was simply a humble opinion

of his own, but he thought perhaps that there were some present who would also agree that there were two distinct diseases. It was very hard to differentiate between them he admitted, but he thought Mr. Buxton was on the right track, and if he could only get an antitoxin or vaccine it would help them very materially, because as they knew the cat was a most difficult patient to handle. They not only bit and scratched, but one could not get them to take any nourishment or medicine like they could other animals.

Mr. ARCHER. It might be said, perhaps, that it did not matter much whether it was one and the same disease or not, but it might do in the treatment of it as it was quite possible that what might be effectual in one complaint would not have any effect whatever in the other. His own impression was that cat influenza was very frequently called cat diphtheria. He was inclined to believe himself, from clinical observations more than anything else, that there was a cat distemper which was really a distinct disease, but he was not prepared to say positively that it was so. With regard to its being transmissible to the human being he was quite convinced that it was, especially in the case of children, and what was more important when cats got these throat symptoms, although it did not give diphtheria to the human being, it did convey to them a septic condition of the throat which people became very alarmed at. It was very important that they should know all they could about this subject, if only that they might be able to assure people whether there was any chance of their getting diphtheria from the cat. Personally he invariably treated it as a communicable disease, and told his clients to isolate as far as possible. With regard to treatment he generally tried sulphurous acid.

Prof. WOOLDRIDGE: What doses?

Mr. ARCHER: Five minims. Another thing he gave was sulphite of magnesia. He was treated with that himself for diphtheria.

Mr. BURT: You have not choked any cats with it yet, I suppose. (Laughter).

Mr. ARCHER: No. He used inhalations of iodine and eucalyptus or terebene in addition to internal medicines.

Mr. ANGWIN. If he might be permitted to make another contribution to the discussion, only last month he was called in to a case by two maiden ladies. These ladies had never had an animal in their house before, but they procured a black cat, and the cat was suddenly taken with the most fearful sneezing. Within a week both ladies were suffering from sore throats. They blamed the cat. He pooh-poohed the idea, but it might have been correct.

Mr. BURT asked Mr. Buxton if he had kept any record of how many fatal cases he had had. Personally he had treated a large number of cats in the course of his experience, but as far as he could remember he had only had about three die from influenza.

The PRESIDENT desired to thank Mr. Buxton very much for his very interesting paper and the information he had given them. He was very much to be congratulated on being the first in the field in this matter, and he was doing an excellent work in an entirely new direction, and on a subject that was really well worth studying. There were several types of disease which had been called cat distemper, but for some years now he had come to look upon this disease described by Mr. Buxton as something different. During the last five or six years he had made a very careful study of the matter, and he was very pleased when he read that Mr. Buxton had taken it up from the pathological side, and that he had actually discovered something which tended to confirm his own views. Mr. Buxton told him that when he had his place full of cats these outbreaks occurred in exactly the same way; and that had been his experience. But he could not understand his freedom from losses because he had found it an excessively fatal disease

among kittens, and when death did occur it occurred very rapidly. If the infection was a virulent one no treatment was of any use. Further, the symptoms were not those of ordinary cat distemper. There was the peculiar dribbling from the mouth and the sneezing which followed, and then when once a recovery began to take place the extraordinarily rapid recovery was quite different from that of cat distemper, where they might have the sneezing go on for a year or two. Then, again, in this influenza as he called it, instead of getting a heavy purulent discharge from the eyes and nose as in distemper, they would get a sudden lesion in the lung forming a croupous pneumonia from which the cat generally died in from twenty-four hours to two or three days.

Prof. WOOLDRIDGE: You get the same thing in distemper.

The PRESIDENT: No, not the same acute symptoms. You will have the lung symptoms going on for a week or a fortnight, perhaps. He was satisfied in his own mind that this disease was something quite different from distemper, as he had always recognised it. He confessed he knew nothing about the pathology of the disease, and he was very glad somebody had taken that up, because if they knew what the organism was, and could prove that that organism was the sole cause of this particular kind of infection, they could then differentiate it from cat distemper by experimental inoculation. He hoped Mr. Buxton, in his reply, would be able to describe it from the ordinary cat distemper by giving them a list of the symptoms as they had occurred in the cases experimentally inoculated.

Mr. BURT mentioned that in Brighton for some years now there had been a cat shelter for the collection of stray cats, and that place was seldom free from this influenza, but he did not think he had ever seen this purulent discharge from the nose, and it was also very seldom that a cat died there. It was very strange that these stray cats should have the vitality to recover when the better bred animals died.

The PRESIDENT, referring to the question of the contagion passing from cats to human beings, observed that he regarded it as nonsense.

Prof. WOOLDRIDGE: That is hardly worth much in the face of positive instances is it?

The PRESIDENT: I have never been able to trace any cases myself. The cat, of all animals, is the most likely to carry an infection in its fur, but if it was merely pharyngitis I should not mind children handling the animal, that is providing, of course, that it was not tuberculous.

REPLY.

Mr. BUXTON desired to thank Prof. Wooldridge for his kind remarks. The latter seemed to be extremely anxious that he should commit himself and differentiate between distemper and influenza, but in the first place he did not know what distemper was.

Prof. WOOLDRIDGE: In that case then you cannot say that this is not distemper.

Mr. BUXTON continuing: Assuming distemper was due to a specific organism, such as that described by Ferry, he could honestly say this disease was not distemper, because *this* particular organism always produced identical symptoms, and that, he believed, was not the rule in cat distemper. Further, if cat distemper was due to an invisible virus he failed to see that this could be the organism, because it was not an ordinary inhabitant of the cat's respiratory track, and if distemper was due to a virus the organisms that were going to cause the secondary lesions must be ordinary inhabitants. The serious part of this influenza lay in the fact that the animal would not look after itself. It did not appear to suffer from any general intoxication, and the effects were purely local, whereas in distemper they certainly were not local. Animals which were

suffering from distemper always showed symptoms of a more or less general intoxication, but in the case of cat influenza they had a coryza laryngitis, and the effects were purely local. Then, again, in influenza they got a high temperature at the very outset of the disease, but afterwards it was very uncommon to get a high temperature unless pneumonia supervened. In the case of a cat suffering from distemper on the other hand they had a high temperature curve that might last over several days, and this high temperature curve appeared to be produced by intoxication, and he had not seen that condition of things in cat influenza. Neither had he seen any caking of the discharge running from the eyes and nose of an animal suffering from influenza, but they got this in distemper. "Contagious catarrhal fever" would be a very good name to give the complaint, but he failed to see any great objection to "influenza." With regard to the transmission of the disease to human beings, he did not think cat influenza ever caused any serious disturbance to the human being, but that it could be transmitted he knew perfectly well, because he had had it three times himself, and his assistants had caught it twice. It was simply an irritation of the nose and eyes, causing sneezing, and some laceration which lasted from 24 to 48 hours, and then went off. He did not know whether it was a coincidence, but each attack he had had seemed to be worse than the previous ones.

Mr. E. WHITLEY BAKER asked Mr. Buxton whether, when he had suffered from this cat influenza, he had noticed any other human being had had it.

Mr. BUXTON: No, and I think there is no question that it was transmitted from the cats.

Prof. WOOLDRIDGE: May I be allowed to emphasise what I think Mr. Buxton means, because I know a little of the conditions under which he does his work. It has only been Mr. Buxton or his assistants who have been associated with him in the handling of the cats that have had it I understand.

Mr. BUXTON: Yes, that is so. The proportion of fatalities among his cats had only been about five per cent., but that was because he had generally had to deal with old cats, and although when he got an outbreak it generally ran through the whole lot, it was only the young cats that got it seriously.

Prof. WOOLDRIDGE remarked that if he might make a further contribution to that afternoon discussion, the conclusion he had been driven to as the result of what they had heard that day was that this disease was the same as that which he had always recognised as feline distemper, but if they must call it *influenza* then he must say that he had never seen a case of *distemper* in a cat. In that case, considering the enormous number of sick cats which he saw every year, he was driven to the conclusion that feline distemper did not exist. In other words, it amounted to practically the same thing, the disease he called distemper was regarded as *influenza* by the President and Mr. Buxton.

On the proposition of Mr. Angwin, seconded by Mr. Caudwell, the Secretary was directed to write to Mr. Toope, of Dover, and inform him that if he was circularising the profession in connection with his candidature for the Council, he could state that he had the support of the Southern Counties Society.

Mr. CAUDWELL subsequently handed round several interesting post-mortem specimens for inspection, and for which he was formally thanked on the proposition of Mr. Angwin, seconded by Prof. Wooldridge.

Prof. WOOLDRIDGE also proposed, and Mr. Caudwell seconded, a hearty vote of thanks to Mr. Basil Buxton for his interesting paper; and a similar compliment to the President for presiding, on the motion of Mr. Angwin, seconded by Mr. Burt, brought the proceedings to a close.

NORTH OF IRELAND
VETERINARY MEDICAL ASSOCIATION
(NATIONAL V.M.A.—IRISH BRANCH.)

The annual general meeting was held on Friday, the 20th March, at the Belfast City Abattoir, Stewart St. Mr. J. A. Jordon, President, occupied the chair, and the following members were present:—Messrs. J. J. Ross, R. Kernohan, J. Ewing Johnston, J. McLean, A. M. Crighton and F. W. Emery.

Apologies for non-attendance were received from Messrs. W. S. Lamont, W. C. M. Smith, A. Monro, J. B. Dunlop, and Capt. Hodgkins, A.V.C.

The minutes of the last meeting were taken as read and confirmed.

REPORT OF COUNCIL.

A Council meeting was held on Thursday, 12th inst. at the Belfast City Abattoir. The President occupied the chair, and there were also present: Messrs. Ross, McConnell, McLean, Johnston, and Emery. Apologies for non-attendance were received from Messrs. W. C. M. Smith, J. Kernohan, and J. McAleer.

Your Council desire to express their deepest regret at the great loss our Association has sustained by the death of the late Mr. J. A. Thompson, J.P., F.R.C.V.S. who for many years so ably discharged the onerous duties of Treasurer to the Society. When the sad event became known your Council took steps to have the Association represented at the funeral and to send a wreath in token of the great regard in which our late colleague was held by every member. Letters of con-

dolence were also forwarded to the widow and family in your behalf.

Owing to this very sad event it was found necessary to postpone the date of the annual general meeting.

Your Council recommend that a further subscription of five guineas be sent to the Treasurer of the International Veterinary Congress in order that the amount originally promised be paid.

It is also recommended that the sum of £2 10s. be forwarded to the Treasurer of the National Association in connection with the scheme of amalgamation.

The undermentioned members of our Association are nominated as office bearers for 1914.

President.—Mr. W. C. M. Smith, Newry.

Secretary.—Mr. J. A. Jordan, Belfast.

Treasurer.—Mr. Howard McConnell, Armagh.

Vice-Presidents.—Messrs. J. Kernohan, Ballymena; F. McRoberts, Camber.

Council.—Messrs. J. J. Ross, J. McLean, J. McAleer, J. Gregg, J. Ewing Johnston, A. M. Crighton, and J. Loughran, J.P.

On the motion of Mr. R. Kernohan, seconded by Mr. Crighton, the report of Council was adopted by the meeting.

New Member. Mr. Esmonde W. Little, M.R.C.V.S., D.A.T.I., was unanimously elected.

Mr. W. P. WALSH, M.R.C.V.S., Magherafelt, was nominated by Mr. R. Kernohan, seconded by Mr. F. W. Emery.

The meeting discussed the forthcoming election to the Council of the R.C.V.S.: the purchase of Registers for the use of the Secretary and Treasurer, and the circular letter of the Hunting Memorial Committee. In connection with the latter it was proposed by Mr. Ross,

seconded by Mr. Kernohan, and passed, that the Treasurer be authorised to forward the sum of two guineas on behalf of the Association.

The PRESIDENT invited the members to make an inspection of the new abattoir, and in conducting them over this very fine and splendidly equipped building gave a very lucid exposition of the methods of procedure adopted in connection with the various works carried on within its portals.

The meeting terminated by a very hearty vote of thanks to the retiring President for the very able manner in which he had conducted the business of the Association during his term of office.

Medical Protest Against the Dogs Bill.

The following is the text of the memorial which was addressed to the Home Secretary, before the second reading of the Dogs Protection Bill, by some of the most eminent physicians, surgeons, and research workers in the country.

"We desire to express to you our strong conviction that the Dogs Protection Bill, which was put down for second reading on Friday, 17th inst., would inflict very severe injury, not only on medicine and surgery, but also on the study of the diseases of animals. We think that we have some right to ask you to oppose this attack on the advancement of medical science and practice; especially as the Final Report of the Royal Commission on Vivisection does not advise the prohibition of experiments on dogs. We are absolutely certain that such experiments are necessary for the complete study of many problems of physiology, pharmacology, and pathology."—*The Times*.

The Spectrum of Alkaloids.

The application of the spectroscope to the elucidation of the structure of the alkaloids as well as to their detection and estimation has an obvious interest for medical men. The ultra-violet end of the spectrum is concerned, for there the absorption phenomena of alkaloid solutions are displayed. Ultra-violet rays are employed, and the prisms and lenses are made of quartz, as the ultra-violet rays are cut off by glass. The alkaloids have very characteristic spectra, and the lines of selective absorption can be photographed. The minutest quantities of alkaloids can be detected, and a permanent impression can be kept of the records which are always available for reference.

OBITUARY

EDWARD COOPER SMITH, M.R.C.V.S., Hollist Stud Farm, Midhurst, Sussex. Graduated, Lond: April, 1865.

Mr. Smith died on April 15th, at Eastbourne, from malignant disease of the cæcum. Aged 69 years.

HENRY HOWSE, M.R.C.V.S., Newland, Lincoln. Lond: April, 1856.

Death took place on April 16th, from senile decay. Aged 80 years.

GEORGE SMITH, M.R.C.V.S., Tunstall, N. Staffs. Lond: April, 1873.

Death occurred on April 16th, at Station Road, Tunstall, from cardiac disease (valvular), at the age of 63.

ALF. PRUDAMES, M.R.C.V.S., Elm Lodge, Linslade, Leighton Buzzard. Lond: May, 1861.

Mr. Prudames died on April 20th, at the age of 76, from old age: influenza, bronchial pneumonia.

PARLIAMENTARY.

PURE MILK.

In the House of Commons on Wednesday, April 22.

Mr. ASTOR called attention to the unsatisfactory state of legislation and administration with reference to the supply and sale of milk and cream in the United Kingdom; and moved, "That fresh legislation is needed to control the supply and sale of milk and cream in the United Kingdom, and that the existing laws should be more thoroughly administered." He said his object was to try to ascertain the intentions of the Government with regard to further milk legislation. If the public realised the necessity of having pure milk they could get it, and get it at a reasonable price. They were told that if they had further milk legislation there was a prospect that the price might be raised. He believed good milk was cheap milk and bad milk was dear milk. Milk was a good medium for transmitting disease, and milk which produced disease was not cheap at any price. The first essential was that the milk must be pure. Pure milk was by far the cheapest and most nutritive food on the market. Yet they had cases of cows so far advanced in disease that they could not stand, and milk from those cows was sold to the public. Ten per cent. of the milk which came to London was tuberculous, which meant that on one day in ten people who drank milk drank tuberculous milk. They desired uniform legislation and regulations throughout the country dealing with dirt, the temperature at which milk was kept, and the age of the milk, which were the three main factors with regard to disease in milk. He wished also to see the compulsory classification of milk into three grades—(a) the best sort of milk, from herds tested and guaranteed free from disease, which could be given with absolute confidence to children in its raw state; (b) safe milk, which adults could drink with impunity, but which having a larger number of bacteria than class (a) might not perhaps be suitable for young children; and (c) all milk which on its merits could not come in either of the other classes. He had had a sample of the milk supplied to the House of Commons analysed and found it was the rare and fruity vintage; for the sample contained 72 million bacteria per cubic centimetre. The danger of tuberculous milk to adults might be exaggerated, but it was difficult to exaggerate the danger to children. It was their interest to build up a healthy race and to see that the children had a fair chance when they started in life. They must see to it that the milk given yielded nourishment and did not give disease and even death to children.

Mr. HILLS seconded the motion. He emphasised the importance from the national point of view, of Parliament taking adequate steps to ensure a pure milk supply, and pointed out that the schemes adopted in New York with this object in view had reduced infantile mortality by nearly 50 per cent. in three years.

The debate was continued by Sir R. Baker and Messrs. Allen, Hume-Williams, H. Hope, and J. F. Mason.

Mr. HERBERT SAMUEL in the course of his reply said:—There was no doubt that the measures so far taken to protect the milk supply were totally inadequate to safeguard the public health, and it was essential that fresh measures should be taken. Any Bill introduced should, in his opinion, substitute for various codes now administered by local authorities the uniform provisions of a general statute. The Bill he hoped to introduce shortly—a Milk and Dairies Bill—would be much more restricted than its predecessors, but would still, he hoped, be effective. He did not propose that milk sellers should be licensed, but he proposed to take full powers to trace back tuberculous milk to its source, and to deal effectually with diseased cows. He was anxious not to disturb the dairying industry, or to raise the price of milk, and the Bill would be framed in that spirit.

RESEARCH : CIVIL PENSIONS.

Mr. C. Bathurst asked the Home Secretary if, in view of the services to the community of the late Mr. William Hunting, F.R.C.V.S., who died on October 24th, 1913, especially in the scientific research which had rendered possible the stamping-out of the disease of glanders, fatal alike to man and horse, the claims of his children (a son and daughter), now without means of subsistence, to Civil List pensions, would be favourably considered.—Mr. McKenna said that, if details were supplied, the case would be gladly considered.

MILK AND DAIRIES BILL.

In reply to Mr. C. Bathurst, Mr. Herbert Samuel said he hoped to be able to introduce the Milk and Dairies Bill shortly, but that he could not suggest a day for the second reading.

Personal.

SEARBY—BOULTBEE.—On the 16th inst., at the Parish Church, Ramsey, Hunts., Bernard Allen Searby, M.R.C.V.S., to Rosalind Francis Evelyn Boulton, elder daughter of the late F. R. Boulton, M.I.C.E., Johore Government Service, and Mrs. Boulton.

WYNN LLOYD—PRITCHARD.—On April 16th, at Salem Church, Carnarvon, by the Rev. D. Stanley Jones, assisted by the Rev. David Hoskins, M.A., L. W. WYNN LLOYD, M.R.C.V.S., to Lassie, youngest daughter of J. R. Pritchard, J.P., of Bryneisteddfod, Carnarvon, and of Mrs. Pritchard.

MARKS—DIER.—The marriage of Miss Gertrude Alice Dier, daughter of Mr. J. B. DIER, M.R.C.V.S., and Mrs. Dier, of East Grinstead, to Mr. Frederick Marks, M.R.C.V.S., son of Mr. H. Marks, of Herne Bay, took place very quietly at the Parish Church, East Grinstead, on Tuesday, the 14th inst. The bride's father is well known and respected in East Grinstead and district, where he has not only practised in his profession, but has taken a keen interest in public matters. He was Vice-Chairman of the East Grinstead Urban Council until he retired this year, and he has also served on public bodies at Danehill, where he formerly lived. The bridegroom has been in partnership with Mr. Dier for the past two or three years, and has during the past twelve months or so carried on the Danehill branch of the practice. The bride was given away by her father. Mr. Ernest Marks attended his brother as best man.—*Southern Weekly News.*

COLONIAL APPOINTMENTS.

Sir,

I quite agree with "East of Suez" in his letter in your issue of 28th Feb. The Colonial Governments are not going to attract the best men when they offer such small salaries combined with indifferent prospects. Do they expect any ambitious young man to waste away his life stuck out on the back of beyond, with no intercourse with brother professionals, pioneering his profession for the sake of posterity and an unappreciative Government surrounded by unbelievers and sceptics? A maximum of £500 per annum does not limit the man engaged in private practice, and in the Transvaal this maximum is just sufficient to enable a married man to keep his head above water by living extremely parsimoniously. Certainly they should be able to engage men at the salary offered, but not the best men with Post Graduate Certificates also, and I believe they expect the best. It is not the salary which attracts but perhaps a desire to travel, to see the world, which operates in most cases, but after the space of a few years, regret comes that one voluntarily exiled oneself, unfitted oneself for private practice and that the only future is to hang on,

devoid of ambition, in the hope of living long enough to enjoy the small pension. I think if the back veldt veterinary surgeons were brought in occasionally for instruction in Dr. Theiler's well equipped laboratory it would keep alive their interest in science and relieve the monotony of their existence.

VOL. XXVI.

FELINE DISEASES.

Mr. Buxton's short paper upon "Cat Influenza," with its discussion by the Southern Counties Society which appeared last week, illustrate how much we have still to learn concerning many of the commonest cases in practice. The catarrhal diseases of the cat are comparatively a minor subject, but their importance to the practitioner is increasing every year, and no group of diseases is more obscure. Some bacteriological work has been done upon them—that of Mr. Buxton seems likely to lead to good results—but much more remains to be done. To the clinician, these affections are a complete mystery. How many specific catarrhal diseases attack cats? Are they distinct diseases, or variations of one disease under the influence of secondary infections? How can they be differentiated clinically? Which of them, if any, represents distemper?—to which should the term "influenza" be applied, or is that term really applicable at all?—and are any of them sufficiently transmissible to man to be of importance on that score? No one can answer one of these questions with certainty—those who attempt answers are merely offering individual opinions.

The near future will probably see an increase in the study of feline diseases in the laboratory. Clinical experience ought to supplement this, but the subject is one of those in which clinical experience loses half its value if it is not systematically noted.

There are men who see these cases daily, and their noted experience might be invaluable. But, without notes, much of that experience would be too hazily remembered to be reliable. Systematic note-taking is tiresome work; but, considering how important feline practice is becoming and how little we know of many of its problems, it is well worth doing.

Lastly, there is still room for further enquiry as to whether the feline catarrhs are transmissible to man. The public are generally inclined to believe in such transmissibility. Many veterinary surgeons flatly deny it; and some who do so are men of great experience. Still, there is some evidence in support of at least a certain degree of transmissibility; and all such evidence requires careful sifting. Much of it is vague, and some probably originates from combinations of coincidence and prejudice: but there seems to be enough to justify us in regarding the question of transmissibility as not yet definitely settled.

SUCCESSFUL TREATMENT OF PROTRACTED PNEUMONIA IN THE HORSE BY IODIPIN.

Many reports have appeared of the favourable effect which subcutaneous injections of iodipin exercise upon feverish toxic infections. The drug is said to cause hyper-leucocytosis, prompt fall of the temperature, and improvement in the general condition. These reports have induced Johannes Schaaf, of Berlin, to try the effect of a 25 per cent. solution of iodipin (which is prepared for veterinary use at a moderate price) in equine pneumonia.

Schaaf's first case terminated fatally, but its course while under treatment with iodipin strengthened his confidence in the drug. He had been treating the horse by other methods for eight days without success. The animal had taken no food throughout the period, and constantly grew weaker. Schaaf injected 50 grammes (about 1-2/3 oz.) of iodipin subcutaneously in the neck. The next day the horse showed an appetite, and took hay and carrots briskly. Schaaf injected another 50 grammes of iodipin, and a keener appetite developed on the following day. The condition then suddenly became worse, and the horse died. Post-mortem examination revealed the existence of a gangrenous pneumonia, against which iodipin would naturally be ineffectual. Nevertheless, Schaaf arrived at the conviction that, had iodipin been used earlier, a gangrenous process of the pulmonary tissue would not have arisen.

In the next case, Schaaf awaited the day of the crisis. As no improvement appeared on the sixth day, he began on the seventh day with an injection of 50 grammes of iodipin. On the same day the animal began to eat again, and the temperature went down. On the following day Schaaf repeated the injection. The appetite remained continuous, and Schaaf gave further injections of the same dose on the third and fifth days. The condition improved daily, the horse regained his strength, the breathing became calmer, and gradually a complete recovery took place.

With the same dosage, Schaaf has since repeatedly successfully treated horses in which he clinically diagnosed an atypical form of pneumonia. He remarks that the fact that the animal recommences to eat after the iodipin injections impresses the owner, and induces him to disregard the relatively high price of the drug.

The injections of iodipin should be begun early, as soon as a typical crisis fails to appear.

Of course, in addition to using iodipin, it is absolutely necessary to strengthen the action of the heart. Schaaf does this by means of daily alternative doses of camphor and digalen. The latter drug

is especially serviceable, as it is given subcutaneously. Very soon after the injection of 10 c.c. of digalen, an improvement in the heart's action, a rise in the blood pressure, and a slowing of the pulse can be observed. But Schaaf ascribes the chief effect to the iodipin, as he has had no losses since using it.

In most cases, in the course of the illness, Schaaf injects 200 grammes of iodipin in doses of 50 grammes each. He warms the preparation well before administration, and employs a wide canula for the injection.

He has never observed abscesses after the injections, but a painful swelling often appears. This, however, soon subsides. After his hitherto successful experience, he warmly commends iodipin for pneumonias running a protracted course.—*Münch. Tier. Woch.*

AN ACUTE SERO-FIBRINOUS POLYARTHRITIS IN SWINE, CAUSED BY TRANSPORT.

Albert Stützel, a veterinary practitioner of Geislingen-Steige, Württemberg, has dealt with this subject in an inaugural dissertation at Freiburg. Many young lean swine were being transported from North Germany into South Germany to be raised and fattened in large feeding establishments in the latter country. A number of these animals which travelled by railway, and had to make a journey lasting from four to five days, regularly showed a peculiar affection of the joints. This occurred so constantly that an unknown contagious disease was erroneously presupposed to exist. A careful investigation took place, in which Mayer, an official veterinarian, bore an especially prominent part, and by numerous post-mortem examinations the condition was proved to be "an aseptic, specific, independent disease of the joints." K. Glässer, in his book on the diseases of swine, states that similar cases of illness have occurred in Hanover, Westphalia, and the Principality of Lippe-Detmold.

According to the results of the investigation, this sero-fibrinous polyarthritis of swine must be attributed to injurious traumatic influences during the long journey, in which long fasting and unsatisfactory accommodation exercise a predisposing effect. The condition is of importance in connection with the differential diagnosis of the scheduled contagious diseases of swine.—(*Berliner Tier. Woch.*)

TRAUMATISM OF THE SPLEEN FROM A FOREIGN BODY.

Dora, of Ebermannstadt, records the case of a cow which for some days had been eating badly, and could only be moved with difficulty. Nothing pathological could be demonstrated in the thoracic organs. The movements of the rumen were sluggish, and the region of the ensiform cartilage was sensitive to pressure. Some days later the sensitiveness had extended to the thorax and over the ribs, and every movement seemed to cause the animal pain. The presence of a foreign body was suspected, and the cow was slaughtered.

Post-mortem, the foreign body was found—a wire about eight inches long, which had penetrated from

the reticulum into the spleen. The spleen itself was vastly enlarged, and its capsule greatly thickened. A portion of the organ was transformed into an abscess, which contained foul-smelling pus.—*Munchener Tier. Woch.*

TUBERCLE BACILLI IN THE GALL OF ANIMALS.

The question whether tuberculous individuals discharge tubercle bacilli by means of their gall has hitherto been little studied. Not long ago it was brought into prominence by some researches carried out by Joest and Emshoff. More recently C. Titze and E. Jahn have investigated the subject afresh, and they have published (*Arbeiten aus dem Kaiserl. Gesundheitsamte*) their results.

They agree with the view of Joest and Emshoff that infection of the blood stream has no significance in connection with the excretion of tubercle bacilli in the gall. It is possible that an invasion of the veins of the portal system may influence the excretion of tubercle bacilli in gall. But the essential cause of the latter event is the existence of tuberculous lesions in the liver. In all the cases in which Titze and Jahn found tubercle bacilli in the gall, with one exception, tuberculous disease was present in the liver or in the portal lymphatic glands.

The tubercle bacilli discharged from the liver may, without great diminution of their virulence, pass into the intestine and from thence into the outside world. Hepatic tuberculosis, therefore, in many cases represents an "open" form of the disease.—(Berliner Tier. Woch.)

(An abstract of Joest and Emshoff's work appeared in *The Veterinary Record* of June 29th, 1912, page 819.—*Transl.*)

PROLAPSE OF THE SMALL INTESTINE THROUGH A RUPTURE OF THE RECTUM AFTER PARTURITION.

Barthe records (*Revue Vét. de Toulouse*) the following case. A powerful Anglo-Arabian mare, after the normal birth of a well-developed foal, showed some agitation, followed by colic, which constantly increased in violence.

Upon his arrival Barthe found the mare lying on the ground. Under the tail and between and behind the hind limbs, coils of intestine were lying upon the straw. These had already been trodden, so that the contents had escaped.

Barthe at once saw that the prolapse was proceeding from the rectum. Rectal exploration revealed a longitudinal rent about six inches in length in the upper wall of the rectum, through which the small intestine had worked out in consequence of the action of the labour pains.

Post-mortem, the uterus was found to be intact. The rectum was filled with balls of fæces, firmly pressed together. It may be assumed, therefore, that the upper wall of the rectum, lying between the sacrum and the mass of fæces, could not withstand the enormous pressure put upon it at the moment of parturition, and especially during the passage of the bony prominences of the foal. After the rent had arisen, during the expulsion of the

placenta, the contractions of the abdominal muscles had pushed the small intestine towards the pelvis and through the laceration.

The administration of a clyster shortly before parturition would certainly have prevented this accident.—(*Berliner Tier. Woch.*)

PROLAPSE OF THE RECTUM IN HORSES.

Heisener, of Greifenburg, has recently treated two cases of prolapse of the rectum in horse. In both cases the rectum was pressed out to about the size of a fist, and the rectal mucous membrane was very swollen and oedematous.

The prolapsed rectum was washed and cleansed with a solution of alum, and returned to its place. A piece of cloth soaked in alum solution, was then placed in the rectum, and a prolapse bandage applied. Both cloth and bandage were removed every two hours, to permit faeces to pass. After twelve hours of this treatment the bandage was removed, and no further prolapse occurred.—(*Berliner Tier. Woch.*)

THE HYPODERMIC INJECTION OF CAMPHOR IN ACUTE RHEUMATISM.

A. Borghesi has published (*Il Nuovo Ercolani*) a communication regarding this method of treatment. He has found that repeated rubbings of camphorated alcohol upon muscles and joints affected with rheumatism often induced recovery without any other treatment. This led him to try the effect of camphor given hypodermically. His method is to dissolve the camphor in almond oil, and add a little ether to act as a general stimulant and to render the solution more fluid and more easy to aspirate with the syringe.

The formula is—camphor $2\frac{1}{2}$ grammes, oil of almonds 6 grammes, and sulphuric ether 4 grammes. (Approximately these doses represent respectively $38\frac{1}{2}$ grains, $1\frac{1}{2}$ drachms, and 1 drachm). These quantities are for one injection, but the dose may be doubled. The injection is made in a place where the skin is thin and loose.

There is no local reaction. After the injection the fever diminishes, the animal recovers its spirits, and the cardiac disturbances disappear. The injections should be repeated for three or four successive days.

This method has given good results in horses and cattle, and is equally beneficial in both generalised and localised rheumatism. The author regards it as more efficacious and more economical than the employment of sodium salicylate. (*Annales de Méd. Vét.*)

W. R. C.

Ultra-violet rays are now being employed on a practical scale for the sterilisation of water and milk, while more recently it has been shown that the rays can produce changes similar to those effected by enzymes. Thus starch has been converted into sugar and albuminoids into soluble proteins as though diastase and pepsin had respectively been employed.

NATAL

VETERINARY MEDICAL ASSOCIATION.

The fourth annual general meeting was held in the offices of the Senior Veterinary Surgeon, Natal, at Pietermaritzburg, on October 24th, 1913. There were present Messrs. Power, Amos, Sharp, Ewing, Hutchinson, Goulé, Harber, Cordy, Woollatt, Johnston, and the Secretary, with the President, Mr. Carless, in the Chair.

New Members. Mr. S. I. JOHNSTON and Mr. W. G. BARNES were nominated and elected.

The officers of the previous year were re-elected as follows:—

President.—Mr. CARLESS.

Hon. Sec. and Treas.—Mr. A. GOULÉ.

An interesting paper was read by Mr. A. F. Harber on the "Surgical and Medical Treatment of Epizootic Lymphangitis, and the possible Conveyers of the Disease from the Infected to the Susceptible Animals." This gave rise to a very animated and instructive discussion.

Mr. AMOS moved that the Association contribute to the International Veterinary Congress to be held in London in August, 1914, and also to the Victoria Benevolent Fund. It was decided that sums of £10 10s. and £5 5s. respectively be forwarded to the Committees of the Funds.

An animated discussion then took place as to the advisability or otherwise of the continuance of the practice on the part of Government Veterinary Surgeons of attending cases for farmers and others to the detriment of the private practitioner.

A further paper was read by the Secretary on the subject of "Sheep Scab," which incited a very interesting discussion. The meeting then closed.

A further informal meeting was held later when, in consequence of his leaving to take up a post for the Imperial Government of India, Mr. Shilston resigned the post of Hon. Secretary and Treasurer, to which Mr. Goulé was then elected.

A. GOULÉ, Hon. Sec.

THE BACTERIOLOGY OF MILK IN RELATION TO INFANT FEEDING AND TO THE TREATMENT OF ALIMENTARY DISEASE.

At a meeting of the Manchester Medical Society held on April 1st:—

Dr. RALPH VINCENT opened a discussion on the Bacteriology of Milk in Relation to Infant Feeding and to the Treatment of Alimentary Disease. He grouped the organisms according to the conditions determining their growth in milk. 1. Bacteria producing lactic acid but not producing gas. This group was represented by the streptococcus lacticus and the bacillus lacticus. The streptococcus lacticus was the typical organism growing in pure milk at 38° C. At a later stage, when the acidity had become too great for the streptococcus, the bacillus lacticus appeared, for this organism was exceptionally tolerant of acid. 2. Bacteria producing lactic acid, carbon dioxide, and alcohol. This group embraced the whole of the colon organisms, and included the bacillus acidi lactici (Hueppe), bacterium acidi lactici (Esten), bacillus lactis aerogenes (Escherich), and the bacillus coli communis. When pure milk was incubated the growth of the organisms belonging to this group was inhibited by the growth of the organisms belonging to the first group. When milk, however, was grossly contaminated by colon organisms these might acquire dominance, and in such cases the curdled milk showed

evidence of gas production. 3. Bacteria growing in "pasteurised" milk—that is, milk that had been subjected to a temperature between 65 and 100° C. The bacillus putrificus and the bacillus lactis aerogenes were examples of this group, and their products were of a highly irritant and dangerous character. 4. Bacteria growing in milk after it had been raised to 100° C. owing to the fact that their spores had not been destroyed. These organisms were found in milk that had been boiled or "sterilised" and in condensed milk. The group embraced a large number of organisms, the chief representatives being the bacillus subtilis, and bacillus mesentericus, and the bacillus mesentericus vulgatus. When they developed in the intestines extremely powerful poisons of an alkaloidal character were created, and the absorption of these poisons produced profound coma and death. The contents of the small intestine were normally acid owing to the formation of lactic acid from lactose by the lactic bacteria. Were it not for this acid condition putrefactive processes would occur. In the soil the conditions were reversed, for putrefaction was the essential process by means of which dead organic matter was decomposed and rendered available for the vegetable kingdom. The lecturer discussed the methods of bacteriological examinations of intestinal dejecta employed at the Infants Hospital, and drew especial attention to the pathological conditions induced by improper diet. When the infant was deprived of the lactic organism naturally present in milk the colon organisms became proteolytic and grave illness resulted. All his observations had gone to show the extreme importance of the milk for infants being given in its raw condition. He believed that the improper feeding with cooked food encouraged the development of tuberculosis, and that the boiling of milk played an important part in the production of diseased conditions in infancy and childhood. Dr. Vincent concluded with a lantern demonstration of numerous photomicrographs illustrating the organisms found in various pathological conditions of the alimentary tract.

Dr. NATHAN RAW said that he did not think it was sufficiently well known that pure milk was sterile, and that the lactic organisms were non-pathogenic. Dr. Vincent's remarks applied to the conditions obtaining at the Infants Hospital, which enjoyed rather exceptional benefits, but in such towns as Liverpool and Manchester it was surely safer to pasteurise the milk before giving it to children. His own observations had brought him to the conclusion that there was a very real danger in such towns of infants contracting tuberculous disease from untreated milk; he would like to ask Dr. Vincent if he did not think that bovine tubercle bacilli were capable of infecting children.

Dr. C. P. LAPAGE said that he would like to have heard Dr. Vincent's opinion on dried milk. He had come to the conclusion that in slum districts it was safer for the milk to be pasteurised than to be given to infants untreated.

Dr. VINCENT, in his reply, said that he was astonished to hear Dr. Raw speak of a "sterile" milk. Neither human milk nor cow's milk was sterile. Collected with the greatest care both milks after about eight hours' incubation at blood temperature normally showed a profuse growth of the streptococcus lacticus. The bacillus aerogenes capsulatus could always be found in cow's milk provided a sufficient quantity of cow's milk was taken. He did not think that the "pasteurisation" recommended by Dr. Raw could be relied upon to destroy tubercle bacilli. He based his statement in regard to cooked milk and tuberculosis simply upon practical experience, not only of himself but of many others. He could not establish any relationship between the consumption of raw milk and the incidence of tuberculosis. On the contrary, he found that children fed on boiled or condensed milk were much more prone

to the disease, especially in its more serious forms. He found it difficult to understand the attitude generally adopted by medical men who favoured the boiling of milk, for they were uniformly silent on the subject of boiling the butter, a concentrated milk product always prepared from raw milk. Practically all the infants attending the out-patient department of the Infants Hospital were fed on raw milk which the mothers obtained from the ordinary milk shops. The infants did extraordinarily well, and the work there afforded no justification for the advocacy of boiled milk. He was inclined to agree with Dr. Lapage with regard to dried milk. If a child had to be fed on a cooked food, then dried milk was better than boiled milk.—*The Lancet*.

At the Infants Hospital, Westminster, on April 21st, as the first of a series of lectures on "Babies," Dr. Ralph Vincent, the senior physician and director of the Research Laboratory at the hospital, spoke on the chemistry of milk.

Dr. Vincent pointed out that milk is practically the only food containing all the elements necessary for an infant's nutrition. He laid particular emphasis on the superiority of uncooked over cooked milk, for in the latter the lactic organism was destroyed. This organism was essential, as it produced an acid by the fermentation of milk and sugar which prevented the growth of putrefactive and other injurious organisms.

The essential requirement for a baby, insisted Dr. Vincent, was clean pure milk in its natural condition.

Electric Treatment of Milk.

At a meeting of the Liverpool Medical Institution Professor J. M. Beattie submitted a paper on "The Electric Treatment of Milk." The two problems to be solved were: 1. Could the pathogenic bacteria be destroyed? 2. Could the milk be turned out free from pathogenic bacteria and yet otherwise unaltered? He described the initial difficulties. He then gave a detailed description of the apparatus he employed. A rapidly alternating current was used, and there must be no eddies in the milk and no cessation of flow. He gave an account of numerous experiments showing the effect on the bacteriological content of the milk. So far milk infected by tubercle had been rendered free from tubercle bacilli and the bacillus coli group. Guinea-pigs were freely used in the experiments. The only bacteria left in the milk were sarcinae, sporing bacteria, and occasional streptococci, the bacilli coli group, and the tubercle bacilli being invariably killed. Careful examination of the treated milk revealed no difference between it and fresh milk, the milk tasted the same and had the same odour as fresh milk, and its keeping power was greatly increased. He stated that the plant was devised and many experiments carried out by Mr. Lewis, of the Bacteriological Laboratory, to whom the success of the experiments was due.

The President (Dr. E. W. Hope) referred to the very large voltage used, and also to the effect that the new apparatus was "tool-proof." The real object of the investigation was the prevention of infant mortality. 25,000 children had been fed from sterilised "humanised" milk in Liverpool in the last 15 years with the most excellent results, but he realised that they had now come to a much better way of dealing with the milk.

Mr. G. C. E. Simpson drew attention to the biochemical aspect of the problem of milk sterilisation, mentioning the work of Fröhlich, Holst, and Funk. His own work had shown that the present method of preparation by the Liverpool Corporation did not destroy all the essential antiscorbutic vitamins of fresh milk. He

suggested a trial of the biochemical properties of the milk treated by the high electric currents before it was used widely.

Dr. R. Stenhouse Williams regarded the method practised by Prof. Beattie as the best yet discovered, since from the chemical standpoint it left the milk practically as in the raw condition. At the same time the question of its effect upon vitamins was in doubt, and the importance or otherwise of this in sterilised milk used for children should be absolutely settled before any such method was officially adopted. In his view the question was whether they ought not rather to improve the methods used in the taking of the milk instead of covering up bad work by sterilisation.

Mr. Golding (Reading) required more investigation from the chemical and biochemical point of view. He mentioned that copper electrodes might erode and precipitate copper in the milk and produce a taint, and inquired if this method had been applied to water, and what the probable cost might be.

Dr. J. Murray Bligh held that the value of the process depended upon the results obtained by feeding the milk so treated to children. Sterilisation of milk was a retrograde movement.

Professor Beattie, in his reply, admitted that a clean milk supply was certainly the ideal, but if it proved impossible to obtain an adequate supply of pure milk then sterilised milk was essential. He agreed that the whole system should be tested for one year before being set up elsewhere.—*The Lancet*.

The Mallein Test for Glanders.

Dr. J. R. Mohler, of the U.S.A. Department of Agriculture, contributes the following letter to *The Breeders' Gazette*, Chicago:—

"You submit to me a letter from one of your readers in which he quotes some unfavourable experiences in testing horses for glanders with mallein. His statements are somewhat exaggerated and furthermore his quotations on the results of the different investigators are not entirely accurate. Thus for instance in Hungary out of 570 reactions 536 showed lesions of glanders on post-mortem, and in other statistics from Hungary out of 1,385 reactors 1,313 showed lesions of glanders. My compilation, which includes many thousands of mallein reactions, showed the test to be reliable in about 90 per cent. of the cases.

While mallein and tuberculin are somewhat similar biological products, the general opinion of those who have had extensive experience with both of these agents is to the effect that subcutaneous injection of tuberculin has proved to be far more reliable in diagnosing tuberculosis than subcutaneous injections of mallein in detecting glanders.

The subcutaneous mallein test has unquestionably accomplished good results, but the fact that a certain percentage of horses free from glanders react to the test has made a more accurate method of diagnosis desirable. The serum tests, which at present constitute the official tests in Germany, are without doubt the most reliable means of diagnosing glanders. In our work the serum tests, known as the combined complement-fixation and agglutination tests, have proved reliable in 99 per cent. of cases. As these tests are delicate laboratory tests they are not available to the practising veterinarians.

We have been for some time engaged in extensive investigations with the ophthalmic mallein test, and from all indications this method will offer the most accurate means for diagnosis available in general practice. It is more reliable and also simpler in its application than the subcutaneous mallein test, and in its inter-

pretation there is less chance for error. Should the eye test give a non-typical reaction, the serum of such an animal may be readily tested by the combined serum tests, which is not the case after a subcutaneous mallein test, since the subcutaneous injection of mallein interferes with the interpretation of the serum test for at least thirty days."

About Mendelism.

In 1791 a Massachusetts farmer, by name Seth Wright, found in his flock of sheep a male lamb with a long, sagging back and short bent legs, somewhat like those of a German dachshund. It at once occurred to this hard-headed Yankee that if he could get together a flock of short bow-legged sheep a good deal of unprofitable labour in the shape of building high fences would be saved, and, incidentally, he would have more time at his disposal for swopping lies about his corn crop and pumpkins, under the verandah of the local country store. So it came about that he mated this curiosity of the flock with ordinary sheep, putting the young ewes back to their own sire. By this means in a very short while he evolved a true-breeding race of short, bow-legged sheep, since known as the Ancon breed.

There are two highly significant conclusions to be drawn from Seth Wright's breeding experiment. We see first that the *male alone* may be the originator of a particular breed, and, secondly, that, without the aid of alternative heredity (Mendelism), Seth Wright could never have built up the Ancon breed from a single male lamb. Had not the characters he desired segregated clean from those of the ordinary sheep which he had to use in the first instances for his females, the new characters would inevitably have become swamped by opposing weight of ancestry.

A similar case may be cited in the hornless breed of Hereford cattle of the United States, which all arose at a place called Atkinson, Kansas, in 1889, from a single hornless Hereford bull. These polled Herefords now constitute one of the bovine aristocracies of America, with a herd-book all to itself.

The British breed of Shorthorn cattle consists of a vast medley of female tap-roots. In fact, any heifer is eligible for the herd-book which can show four pedigree male crosses, and but five are necessary for the insertion of a bull in its pages. For entry in the French Shorthorn herd-book the last sire in the pedigree must have been born in or before 1830, but there is no stipulation about any female tap-root. The Argentine people are satisfied with even less. All that they ask is that the last sire on the female side shall have been born in or before 1845, and there should be no unregistered males in the pedigree after that date.

What are the tap-root of the Hackney, the Shire, or the Clydesdale? There is every sort of a mare at the bottom of the Hackney's pedigree; and yet there is no domesticated animal which breeds as true to his own particular type. Again, the Shire horse owes his characteristics solely to his Flemish male ancestors. A little over a hundred years ago there was not a single heavy mare in the hands of a Lancashire farmer, and yet the light mares of the county are the female tap-roots of the weighty and hairy-legged breed of Shires! Finally, the Clydesdale arose from a cross of the Highland Garron and Flemish stallions introduced by one of the Dukes of Hamilton.—*L.S.J.*

Cocconut Residue as Cattle Food.

After the extraction of the fat, which is used in the manufacture of industrial products, like soap, candles, etc., the residue is compressed into a cattle-food cake. The greater part of the cocconut cake made in England

and on the Continent finds a ready sale in Continental markets. The following analysis is taken from a recent publication called *Invest in the Tropics* :—

	Fats.	Carbo- hydrates.	Albu- minoids.	Water.
Cocoa cake	11.2	47.4	18.2	9.4
Oil palm „	9.5	55.4	16.1	10.5
Linseed „	8.9	27.5	24.8	12.2

Cavalry Remounts—Canadian Horse-breeding Scheme.

The Government have authorised the Militia Department to lease to the National Livestock Exchange 65,000 acres of land 60 miles north of Medicine Hat and south of Red Deer River, for the purpose of collecting and producing thereon half-bred cavalry remounts. The company will pay an annual rental of two cents, an acre, and must produce from thoroughbred sires or thoroughbred mares remounts to the number of not less than 1,500 each year after 1916. The Government of Canada are to have a right of pre-emption in respect of all horses raised by the Exchange, and the company must hold and mature until the age of 3½ years all horses which the Militia Department may desire for military purposes. The price to be paid is not to exceed 250 dols. (£50) a head.

It is further agreed that the British War Office may have pre-emption rights at the same prices and terms in respect of such horses as remain "after the Minister has made his choice."—*The Times*.

The Mule in U.S.A.

The mule is without equal for work in the mines, logging camps, or for trucking and delivery purposes in the large cities. He is a hard worker and, contrary to popular supposition, is one of the most tractable work animals. The idea that the mule is unruly is without grounds; breeders and farmers who have worked thousands of them assert that mules that are downright shirkers of work are not common. Where the mule is well treated as a colt he develops into a willing worker that possesses the ability to resist disease, to withstand the strain of severe labour, and to accomplish more work on less feed than can the horse. Where comparative estimates have been made it has been found that a much lower percentage of mules are bad-mannered than of horses. A particularly commendable trait in the make-up of the mule is that he takes good care of himself, with the consequence that one rarely hears of a sick mule. You seldom hear of one being troubled with founder or dying from colic, simply because this beast is intelligent enough to know when he has eaten sufficient feed; once his hunger is satisfied nothing will induce him to eat more. Unlike the horse, the mule is not attracted by the uncovered grain bin.—*The Ohio Farmer*.

The Cost of Swine Fever.

At a recent meeting of the Central Chamber of Agriculture, Mr. C. Bathurst, M.P., said that, in answer to a question of his, Mr. Runciman had stated that during the five years (1903-1907) prior to the issue of the existing Orders, there were 7,107 outbreaks of swine fever, as compared with 11,207 during the five years (1909-1913) since the issue of those Orders. During the five years prior to the issue of the Orders there were 36,046 pigs slaughtered as diseased or exposed to infection, and during the five years since the issue of the Orders there were slaughtered 131,980 pigs. With regard to the cost of administration and compensation, the figures were as follows :—Compensation during the

first year that the Order was in operation (1908-9), £17,170; administration, £39,608. In 1909-10, £18,53 for compensation, and £44,244 for administration. In 1910-11, £21,288 for compensation, and £48,669 for administration. In 1911-12, £51,351 for compensation, and £62,059 for administration. In 1912-13 there was slight falling off in the compensation, owing probably to the reduction in the pig population. There was £46,952 for compensation and £66,390 for administration. These figures made a grand total throughout those five years of £423,262 out of public money expended in compensation and administration.

The pig population was steadily decreasing in this country, unlike any other country in Europe. The national Bill for the extermination of the disease was steadily rising, and the trade in pigs was equally constantly declining. The Board of Agriculture could not stamp out this disease, and for this reason—the disease existed in a large number of animals which showed no obvious or discoverable symptoms of the disease whatever, and such pigs were capable of spreading the disease to others. It was impossible to defend the existing vexatious and harassing restrictions when there was the possibility of the disease being spread from pigs which showed no sign of the disease.

Mr. Wood Homer pointed out that before the Order of the Board five years ago there was in operation a system of local control which many of them thought more efficient than the control effected by the Swine Fever Order, and Mr. Bathurst admitted that the present system had proved less efficient than the local control was.

A Veterinary Scheme for Co. Dublin.

At the April monthly meeting of the County Dublin Farmers' Association, Mr. McGrane introduced the subject of a scheme of veterinary attendance and advice for members on special terms. He pointed out that the desirability of making some definite move in this direction could not be gainsaid, and he understood that they would find a hearty co-operation from the members of the veterinary profession if a start were made.

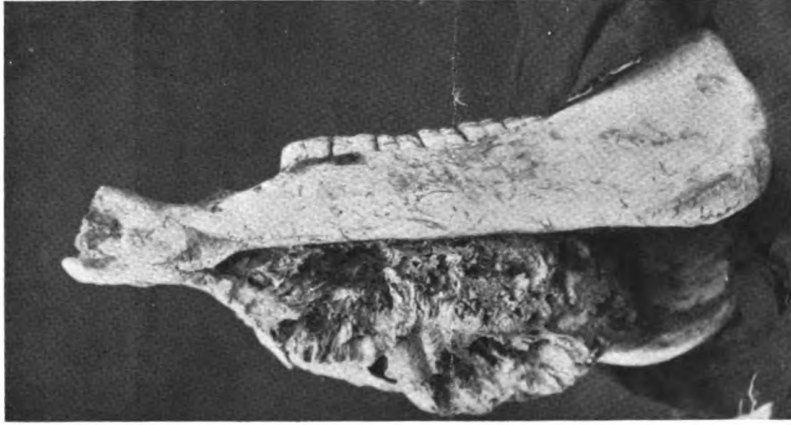

Mr. Grimes stated that he was strongly in favour of a move being made in the direction intimated, and said that already they had been in consultation with the Veterinary Medical Council of Ireland.

Eventually it was proposed by Mr. McGrane, seconded by Mr. Grimes, and passed :—"That a small committee be appointed to formulate a scheme for veterinary attendance."

Dairy Calves—A suggestion.

The following is quoted from *The Breeders Gazette*, Chicago :—

"It is a serious loss to the country to breed nearly all these cows to either scrub or dairy-bred bulls, making it almost necessary to sell the calves for veal. One cow during her life should produce eight calves. On an average four of these will be males and four females. The keeping of one of these four females for the dairy herd would maintain such a herd at constant size, with no losses from disease. The keeping of two heifer calves out of every four heifers born should be enough to permit a certain amount of culling and allow for an increase in the herd. Why not then breed half the cows on our farms to dairy-bred sires, vealing the male calves and retaining the heifer calves for the herd? If the best half of the cows were to be bred to a dairy sire and the other half to a beef sire, feeding all the offspring from the beef sire for beef, we should be following a system which would reproduce the highest efficiency in beef and dairy produce."

The accompanying photos show an osteosarcoma of actinomycotic origin on the jaw of a four-year-old filly. The condition was produced in less than a year.

Splenectomy and Increased Resistance to the Tubercle Bacillus.

Some striking experiments upon the results following removal of the spleen in mice and rats, which appear to demonstrate an increase in the power of resistance to the tubercle bacillus, have been recorded by Lewis (Paul A.) and Margot (A. G.) in the *Journal of Experimental Medicine* (1914, Vol. XIX., p. 187). Into the peritoneal cavity in 21 albino mice was injected a culture of bovine tubercle bacilli; the quantity varied from 1 to 5 mgr. in different animals. Within a time varying from a few hours to a few days all these animals died, and post-mortem examination showed extensive infection of many organs. A similar proceeding applied in 13 mice of similar weight, from which, however, the spleen had been removed, but which had fully recovered from the effects of the operation, showed that a marked lessening of the effects of the inoculations had occurred. Four of the animals were still living at the time of writing, and the rest survived a longer time than did the non-splenectomised animals. Further, the range of infection was more limited in the body. Similar results were gained in rats. In order to test the strength of the possible objection that the mechanical effect of the removed spleen altered in some way the character of the peritoneal inoculation, a second series of animals was inoculated into the pleural cavity. Ten controls all died; of the ten splenectomised animals, two survived, and the rest, again, lived for a much longer time. In this series, too, the range of infection was limited. Similar experiments upon guinea-pigs and dogs were not successful, and the same results were not gained.—*The Lancet*.

Magnesium Sulphate Treatment of Tetanus.

It has been shown that tetanus antitoxin is incapable of combining with and neutralising tetanus toxin when the latter is anchored to the nerve cell. For this reason anti-toxin does not appear to exert any curative action in severe cases—at all events, after the symptoms are well marked. Recent researches have brought to light two other methods of treating severe tetanus—the magnesium sulphate treatment of Meltzer and Auer, and the carbolic acid treatment of Baccelli. The magnesium treatment depends on the anæsthetic effect of magnesium in the animal body. When applied intramuscularly or intravenously, the sensory nerves are first paralysed, then voluntary movement is arrested, next the respiratory centre is paralysed, and lastly, if the animal be kept alive by artificial respiration, the muscles of deglutition and the vasomotor centres are paralysed. After subcutaneous injection, the anæsthesia which follows is flaccid and respiratory paralysis sets in later, while when applied directly to a nerve trunk it acts like cocaine in cutting off the nerve path. It has further been shown that the symptoms and signs of magnesium anæsthesia can be completely checked and removed by injections of calcium salts. It appears from the pharmacological experiments that the circulation is but little affected in magnesium poisoning. Respiratory failure can be arrested by the application of physostigmin or by insufflation of oxygen. Further, it has been shown that in anæsthesia produced by lumbar injections of magnesium salts washing out the lumbar sac suffices to remove dangerous symptoms of respiratory failure. The depressant effect in tetanus was first studied in animals and was then applied to man, 25 per cent. solutions of magnesium sulphate being injected in doses of 1·2 c.cm. per 10 kg. body weight.—*Brit. Med. Journal*.

Augmentation of Bacterial Toxicity by Distilled Water.

In 1912 Hort and Penfold, working in the former's laboratory at the Lister Institute, brought forward evidence to show that variation in the volume of the diluent has a profound effect upon the toxic action of bacterial cultures. If, for example, constant fractions of a broth culture of *B. typhosus*, suspended in small constant volumes of freshly distilled water, were injected intravenously into healthy rabbits, it was found that the toxic effect as expressed in fever was also constant. If, however, the small quantities of water were replaced by large quantities—the fraction of broth culture remaining constant—it was found that death often ensued in an hour or two. Control observations showed that neither fever nor death was ever produced by injection of pure water alone, either in small or large quantities—that is, within the limits recorded. Death never followed the injection of small fractions of broth culture either alone or in small quantities of water. A similar augmentation of toxic effect was also produced, though not constantly, by substitution of normal saline for water. Finally, it was shown that the effect could be produced by injecting the water or saline before the broth cultures. In a paper appearing in our issue of Feb. 14, Penfold and Violle record the results of further experimental work conducted on similar lines. These authors now show that distilled water administered simultaneously with, or prior to, the culture or filtrate markedly increases the toxic action of many organisms, and notably of the cholera vibrio, with which the majority of the experiments deals. Extremely minute quantities of culture or filtrate which would, if given alone, be completely atoxic are rendered acutely and fatally toxic when administered with distilled water. With regard to the explanation of this action, the authors show that hæmolysis of red cells plays at least some part. Administration of the culture with a quantity of lysed red cells, which by itself would be quite atoxic, produces fatal intoxication. It is well known that many cholera strains secrete a hæmolysin, while other organisms which do not possess this power are, however, able to break down red cells when growing in actual contact with them. It is possible, therefore, that the form of intoxication described by Hort, Penfold, and Violle may shed some light on the etiology of certain types of bacterial intoxication which at present are little understood. Doubtless, also, it may have an important bearing on problems associated with anaphylaxis.—*Brit. Med. Jour.*

A New Physiological Hæmostatic.

Attention is drawn in a recent number of *Il Morgagni*, No. 17, March 22nd, 1914, Milano, to the use of the fibrin ferment of the blood as a valuable hæmostatic. This substance is to be found in all the cells of the organism and extracts of all fresh organs contain it. As prepared by Zanoni it exists as a fine powder, of a colour varying from light to dark yellow, slightly unctuous to the touch, and with an odour like that of goose fat. It is slightly hygroscopic and but little changed by light and air, sparingly soluble in water and chloroform, and less still in 95 per cent. alcohol. Aqueous solutions are not limpid, are markedly opalescent, and leave an insoluble residue; they cannot be filtered since most of the ferment remains on the filter. They must therefore be used as they are. This substance which Zanoni has named "coaguline," reduces the time required for the formation of blood clot from 15 minutes to 1 minute. In other words, the blood coagulates almost immediately in the presence of coaguline, and

this power is retained for at least five to six months when it is preserved in the form of powder; after this it gradually diminishes. Certain preparations, however, have remained strongly active even after a year or more. The coagulating power of coaguline resists heat to a certain extent, for even after heating the powder or solution to 95°C. in a water bath its activity is still manifest, although somewhat weakened. This necessitates the time and temperature for sterilisation being reduced to a minimum. To ensure a full hæmostatic action it is not enough to apply the powder or solution to the bleeding surface since the blood would wash it away before it had time to complete its coagulating action; it must be kept *in situ* for a short time with a pledget of cotton or gauze and with slight pressure. The solution can be injected into cavities and operation wounds, but for hypodermic use a solution having an insoluble sediment is not suitable. To obviate this the author found that by incorporating the coaguline with sugar an opalescent solution could be obtained with water which could be sterilised by heating.

The Effects of Light on Bacteria.

The experiments of Mme. Victor Henri, which have led to the discovery that the character of bacteria can be changed by the action of ultra-violet light, receive confirmation in this country by somewhat similar effects that have been recently produced with visible light of longer wave-length. Bacteria have been grown continuously, and repeatedly sub-cultivated, under the influence of certain definite regions of the spectrum, with remarkable results both on their colour and on their size and rate of growth.

The most interesting results were perhaps those obtained with yeasts; fermentation in shallow vessels flooded with deep orange light took place with nearly twice the ordinary rapidity, but violet light was found to retard the process. Bacteria of pronounced colours, due to natural pigmentation, have also been cultivated in tubes placed under the direct rays of the spectrum, and in some cases the colour of the bacteria has disappeared. Orange-coloured cocci treated in this way and grown in blue light for several weeks became perfectly white, and their loss of pigmentation appears to be permanent, as when grown again under normal conditions successive sub-cultivations remained white. Their pathogenic properties have not so far been tested, but it now seems probable that these also would be changed.

The Craze for Appendicectomy.

To the Editor of *The British Medical Journal*.

Sir,—The writings in the *Journal* prove that the damage which is done to the abdominal wall in removing diseased appendices is necessary; it is also plain that the abdominal wall should not be wounded to remove a normal appendix. The question at issue is one of skill, the ability to diagnose a diseased appendix.

It is to be regretted that surgical interest in the function of this caecal vestige has become less and less as the erroneous deduction of the lymphoid hypothesis has tended to mask the true nature of the appendix; for the study of the vestigial nature of the apical portion of the human caecum throws a flood of light on the diseases of the large bowel in relationship to their causation and treatment.

It is not well recognised that man's digestive tube has been evolved to deal with a combination of carnivorous and herbivorous foods, and that neglect of the latter fact is responsible for the diseases of the large bowel and for dental decay.

Our authorities openly avow that they do not know the function of the ileo-caecal valve, a structure that was evolved when ancestral man was compelled to eat coarse herbage, for the purpose of preventing the regurgitation of caecal content into the ileum, to the hampering of the function of the small gut—namely, that of absorbing ingesta which the stomach had prepared for absorption. The function of man's caecum is to digest coarse vegetation; it reached its highest development when ancestral man ate uncooked herbage. During the digestion of such material much gas is generated and the tension ruptured the external muscular coat in the region of the ileo-caecal valve. In the atrophied caecum of civilised man the ruptured part of the caecum exists as the banded caecum and its unruptured apical part as the vermiform appendix. The peculiarity of the ruptures sustained by the human caecum explains the extreme rareness with which the vermiform appendix appears in the animal kingdom; it occurs only in man, a few anthropoid apes, and the wombats. The changes in the human caecum are all traceable in the primate mammals. They accentuate the fact that appendicitis is primarily due to lack of coarse vegetation in the food of civilised man; they indicate that diseased appendices are often associated with large bowels that are weakened from long disuse. Perhaps the severest criticism that can be made against the surgery of the vermiform appendix is that the scar in the abdominal wall is a sign of man's stupidity in not eating that food for which his digestive tube has been evolved.—I am, etc.,

WALTER STAPLEY, M.D., M.R.C.V.S.

Cambridge, New Zealand.

REVIEW.

THE COMMON COLIC OF THE HORSE, THEIR CAUSES, SYMPTOMS, DIAGNOSIS, AND TREATMENT.—By H. CAULTON REEKS, F.R.C.V.S., Examiner in Pathology and Bacteriology to the R.C.V.S. Third Edition. Crown Octavo. Pp. xvj. + 369. Thirty-two Illustrations, many of which are new. Price 6s. net. (Baillière, Tindall & Cox, 8 Henrietta Street, Covent Garden, London).

It is now nearly twelve years since Mr. Reeks first published this book. Hardly any veterinary work has been more widely read and discussed since then, or has exercised more effect upon everyday practice. Its teaching is far from being universally accepted, but there is no doubt that it has profoundly modified the ideas and methods of many clinicians who certainly would not endorse the author's views in their entirety. That being so, a new edition is always welcome, and the present one—the third—is rendered all the more so by the inclusion of much new matter, some of it highly controversial.

The work is so well known that a review may fairly be confined to the new matter. This comprises six chapters, amounting altogether to over 100 pages. One chapter deals with subacute obstruction of the caecum, three with displacements of the double colon, one with the possibility of spontaneous reduction of the bowel in torsion, and one with the comparative rarity of enteritis.

In the chapter upon caecal obstruction, the four cases seen by Professor Gofton (who gave the first clear account of the condition in 1912) are described. One case of the author's is added, with much detailed discussion—largely based upon the work of Major-General Smith. The author thinks that these cases may be commoner than is supposed, that at present they should not be regarded as necessarily hopeless, and that their causation may be explained by adopting Smith's heterodox view of the passage of food direct from the ileum

into the colon. If the latter is the common course of the food—and there is much to support Smith's view—it is easy to see that interference with it may cause cæcal impaction. This chapter is valuable, and the succeeding one upon displacements of the double colon is more so. Space enables us to say very little of these. Mr. Reeks regards displacements of the double colon—including slight displacements or partial twists—as very common indeed. Diagnosis and treatment are fully dealt with, and the section contains a detailed account of the Continental method of reducing such displacements by rectal manipulation. So far as we know, the author is the first Englishman to attempt this procedure, and his experience, which includes some successes as well as failures, is reported with commendable frankness.

In other pages the author maintains that spontaneous reduction of some intestinal torsions is possible, and regards the cases often diagnosed as enteritis as nearly always due to strangulation from partial or complete twist. The new illustrations are all helpful, and altogether the fresh matter alone is well worth the cost of the whole book.

In future editions, some recasting might be advisable. Passages still remain from the first edition which—considering the later development of the author's views—might now be deleted without loss. Again, we should like to see a fuller account given of stomach tubes, and we think that the work ought now to include some consideration of verminous colic. But we can only describe the present edition as likely to be even more suggestive and valuable than its predecessors. Controversial it

still is, and will probably always remain—the added chapters certainly do not make it less so. No book has done so much as this one to stimulate practitioners to examine and think out each individual case of colic as a separate problem, and that invaluable feature becomes more marked with each edition.

* As Diseased or Exposed to Infection

"Research."

In recent years the word Research has grown as familiar in our ears as "Art" and "Hygiene" were in the not distant past. One is apt, from mere habit, to associate the term mainly with Chemical and Biological problems connected with medical work, but work goes on continuously in other directions, and not the least valuable are those links which connect up "pure science" with practical utility. In *The Popular Mechanics Magazine* is given a brief account of recent additions in this direction to the University of Pittsburgh, U.S.A., from which the following excerpt is taken. It is just one more example of the appreciation of the abilities and enthusiasm of the younger men in other countries which is so wastefully lacking in Great Britain.

"How can we make better bread?" asked a big baking company of the late Prof. Robert Duncan, director of the Mellon Institute. The first step in finding the answer was to put a trained chemist at work in one of the institute's laboratories. The baking company paid him a salary of 750dols. a year for two years, and offered him a prize of 2,000dols. if he found a satisfactory answer.

Before he had finished his experiments, another baking company asked the same question. They offered 4,750dols. a year for two years and a prize of 10,000dols. for any practical results. And the chemists got results—found not only one answer but a dozen answers—found how to make better bread, while at the same time cutting down the cost of manufacture; found how to make "salt-rising" bread of better quality than the kind grandma used to make. They found out, in short, so many interesting and valuable facts about the chemistry of breadmaking that the companies which are now utilising these facts are already saving probably more than 250,000dols. a year in the cost of their produce and giving their customers better bread than they have ever had.

INDUSTRIAL FELLOWSHIPS.

Dr. R. K. Duncan, at that time Professor of Industrial Chemistry in the University of Kansas, suggested in 1907, in a book on chemical problems, that a practical means of giving American industry the benefit of the best scientific research might be found in the establishment of what he termed "Industrial Fellowships," in some university.

He proposed that the manufacturer should lay his particular problem before the university authorities, paying an annual sum sufficient to provide a fair salary for a skilled research worker for a limited time, and offering a prize either in the form of a cash bonus or an interest in the profits derived from the discovery, if the problem were solved. Several manufacturers took up the idea, and a number of industrial fellowships were established at the University of Kansas. The idea spread, the University of Pittsburg invited Dr. Duncan to take charge of similar work at that institution, and the Mellon Institute is the result. Secrecy is the rule at the Mellon Institute—the protection of the trade secrets of the manufacturers in whose interests the research work is being done, in order that they may reap the benefits of their investments in the fellowships. Yet every contract between an industrial company and the Institute contains a provision insuring the eventual publication, after a reasonable lapse of time, of the results obtained, for the benefit of the whole industrial world.

"We are now testing, in a unit plant, a new method of extracting copper at a profit from 'tailings' and low-grade ores, which were formerly of little or no value.

Some of our fellows have made important discoveries relating to the hardening of fats by catalysis. An interesting research now under way deals with the purification of sewer grease for use in soap making."

"The utilisation of leather scrap; a method of making glass of a new and distinctive colour; the whole subject of the chemistry of glue, of which little is known; methods of coating steel with copper; questions dealing with the utilisation of natural gas; the production of cement, and the corrosion of steam radiators—these are among the practical, present-day industrial problems which are being attacked under these industrial fellowships. Most of them will be solved. There have been but two failures so far to get the results sought, and these were such as to reflect no discredit on the institute."

Brain in Birds.

The brain in birds is large in proportion to the body. If we admit that intelligence depends upon the weight of brain, then the goldfinch must be placed about the top of the list of birds. In this handsome, clever, and active fellow, the brain weighs one-fourteenth of his whole body. It must be remarked, however, that attempts to draw conclusions as to the intelligence of certain birds from a comparison of the weight of the brain with that of the body have been considered futile. In man, the brain forms from 1-22d to 1-33d of the whole body; in the canary, 1-14th; the sparrow, 1-25th; the chaffinch, 1-27th; the redbreast, 1-32d; the Amazon parrot, 1-42d; the blackbird, 1-68th; the duck, 1-257th; the eagle, 1-260th; the goose, 1-360th; the domestic hen, 1-412th. The goldfinch can be taught to perform a number of tricks. He can draw up water and food by an apparatus designed for the purpose; he can pretend to be dead; and, without showing fear, he succeeds in firing off a cannon. By some, the preternaturally cunning raven is supposed to be the most highly developed of birds. His courage is so great that the eagle respects it; and his intelligence prevents him from getting into unseen though suspected dangers.

Flies and Disease.

Dr. Edward Halford Ross lectured recently before the Royal Society of Arts on "House Flies and Disease." In describing the work of his brother, Sir Ronald Ross, on malaria, he told in detail the story of how the town of Ismalia on the Suez Canal was converted from a deadly to a perfectly safe place.

Research has shown that flies may convey ophthalmia, cholera, tuberculosis, swine fever, and possibly diphtheria and small-pox. They also carry the deadly summer diarrhoea of children which in 1910 killed 1,811 children under two years of age in London.

"At Cairo, during the spring of 1909, Dr. Ross said, 'When I was health officer of that city there, the summer was ushered in by a heat wave on May 1, and the temperature rose to 102° F. in the shade. Fourteen days later the greatest plague of flies ever remembered appeared in the city. Food, milk, and fruit were contaminated by them. Then began the illness and death of the newly born, not only the first born as in the Biblical story. In two months 3000 children under five years had succumbed to enteritis.'"

Mr. HUGH FERRIER, the Corporation veterinary surgeon, reported to a meeting of the Public Health Committee of Dundee Town Council that glanders had broken out in the city, and the Committee decided to shut off the water in the street drinking troughs for a period of three weeks, and to advise horse-owners to carry pails for providing their horses with water while at work.

Sterilization of the Hands by Thymol.

Monzardo (*Gazz. degli Osped.*, Nov. 13th, 1913) points out some of the disadvantages of the iodine treatment of the skin (staining, skin irritation, and hardening), and then describes a treatment he has used for the last year. This consists in the use of an alcoholic solution (5 per cent.) of thymol, used pretty much in the same way as iodine. The author has performed 100 hernia operations, 53 laparotomies, and many surgical operations, as well as obstetric work, under his method of disinfection, and is well satisfied with the results. The solution, he says, is non-toxic non-irritating to the skin, does not affect instruments, and is at least as powerful as iodine as a disinfectant.—B. M. J.

The Local Names for Sheep.

The following list of the different names, according to age, sex, etc., given to sheep may be useful as well as interesting.

From birth to weaning the male is variously called a "tup-lamb," "ram-lamb," "pur-lamb," or "heeder"; if castrated, a "hogg-lamb." The female is a "ewe-lamb" or "gimmer-lamb." Generally a sheep is a lamb until weaned; but in the South of England, and especially among the Kent or Romney Marsh "keeping" sheep, the animals are "lambs" until they are a year old; the keeper taking lambs, wethers, or ewes, as the case may be, although the former are, of course, weaned long before sending out for winter keep.

From weaning to first shearing the male is a "hogg," "hogget," "hagerel," "hoggerel," "tup-teg," "lamb-hogg" or "tup-hogg"; if castrated, a "wether-hogg" or "he-teg." The female is a "gimmer-hogg," "ewe-hogg," "sheeder-ewe," or "ewe-teg." Hogget wool is wool of the first shearing, but in these progressive days lambs are sometimes shorn in the first year, and this is calculated to introduce some confusion.

From the first to second shearing the male is a "shearing," "shearling," "shear-hogg," "dinmont," "diamond ram," "ram-tup," or "one-shear tup"; if castrated, a "shearing-wether," "shear-hogg," "wether-hogg," "wedder-hogg," or "two-toothed wether." A female is a "shearing ewe," "shearing-gimmer," "theave," "gimmer," and "double-toothed ewe or gimmer." A "yeld-ewe" is one that has ceased to give milk, and a "draft-ewe" or "draft-gimmer" is one that has been drawn from the breeding flock.

From the second shearing to the third the male is a "two-shear ram," etc.; if castrated, a "four-toothed wether" or "two-shear wether or wedder." A female is a "two-shear ewe." She is a ewe if in-lamb; if not, a "barren gimmer"; or, in Scotland, if not put to the ram, a "yild gimmer." From the third to fourth shearing the male is a "three-shear ram or tup"; if castrated, a "four-toothed wether" or a "three-shear wether"; if female, a "three-shear" or "winter ewe."

Afterwards the ram is an "aged tup"; the wether "full-marked" or "aged"; and the ewe, aged or "three winter." In the North "shearing" is employed as indicating age, while the south countryman speaks of "teeth," the term, of course, having reference to the eruption of the permanent incisors. Quite recently we met a farmer who, until he received ocular demonstration, refused to believe that a sheep had no incisor teeth in the upper jaw. It may be news to others to learn that both sheep and cattle are there furnished with what is called a dental pad instead of teeth.

VETERAN, in *Farm and Home*.

The Horse in U.S.A.

Says an American journal, "The horse is coming back. In all sections of New York, especially on Broadway and Fifth Avenue, the horse-drawn vehicle, public and private, is coming into its own again. The novelty of the automobile is wearing off along with the price, and people who ride for pleasure are turning back to man's tried and true equine friend. With the horse the hansom cab is coming into favour again, and they may be seen now in large numbers before all the big hotels and at the public hack stands. Five times as many horse cabs are in evidence now in New York as were used a year ago."

TRENCHARD—WARE.—On 28th April, at St. Mary's Church, Bridgwater, by the Rev. W. E. Catlow, Hugh, eldest son of Hugh Trenchard, J.P., of Enfield, to Dorothy, youngest daughter of the late Edwin Ware, M.R.C.V.S., Consulting Veterinary Surgeon to the County of Somerset, and Mrs. Ware of Bridgwater.

Mr. DAVID ROWBOTTOM SOWERBY, M.R.C.V.S., of 105 Anlaby Road, Hull, for many years an Inspector, under the Board of Trade, of the Exportation of Horses, left estate of the value of £9,815.

PRESENTATION TO MR. JOHN BROWN, F.R.C.V.S.,
INVERGORDON.

Over a hundred people, representative of all classes in the agricultural community, gathered in the Royal Hotel, Tain, on Friday, April 3, when the presentation was made to Mr. John Brown, F.R.C.V.S., Invergordon, who for over 20 years now has been the untiring servant of the agricultural community of Ross-shire and Sutherlandshire and particularly of Easter Ross.

Recently a committee was formed to arrange for a presentation to Mr. Brown. Mr. W. G. Paterson undertook the duties of convener, and Mr. A. B. Davidson, Kincaig, the secretaryship, with the result that a handsome sum of money was collected, and the promoters were able to give Mr. Brown a motor car, which in the circumstances is the most suitable gift that could have been provided.

Mr. Paterson, in making the presentation, said he thought they could congratulate themselves on the successful termination of the work which they undertook. When the project was first started there was a large and influential attendance, and from that moment the promoters felt that they would have no difficulty in carrying out what they wanted. He was glad to say that they had been more than able to realise their aims: they were now able to present him with a car

and it would be the most useful gift they could give him. Mr. Brown had been in the district for over 20 years. He came as a young man, fresh from college, and newly off the irons. He had the good sense to choose Invergordon, and there he had abided. After a little time they found he knew his work very well, and they appreciated his abilities. During the past twenty years their appreciation had increased yearly, and they had profited by his experience. But experience was not enough in his profession. The profession was rising daily, and Mr. Brown had certainly kept himself up-to-date. He thought the honour done that day to Mr. Brown was just what was wanted to show him how the farmers of Easter and Wester Ross appreciated him. In conclusion Mr. Paterson said—In the name of the subscribers I have pleasure in presenting you with this motor car, and I am sure it is the wish of all that you will enjoy good health, and that it will be a comfort to you in the wide district over which you operate. (Loud applause.)

Mr. Paterson said he had another pleasant duty to perform—to present to Mrs. Brown a silver service. They had hoped from the beginning that they would be able to associate Mrs. Brown with the presentation, she had helped Mr. Brown very much in his work. They were delighted that they had been able to give her those things. They wished Mr. and Mrs. Brown long life and prosperity. (Loud applause.)

The inscription bore the following—"Presented along with a motor car to John Brown, F.R.C.V.S., and silver tea service, entree dishes, and set of cruets to Mrs. Brown, in recognition and appreciation of the services rendered to the agricultural community of Ross and Sutherland."

Mr. Brown, who was received with applause, said:—Mr. Chairman and gentlemen, I feel I have no words to adequately express my feelings of gratitude for the very kind words you have said about me, and for the very handsome and useful gift you have presented to me. Ever since I came to reside in Ross-shire I have experienced the greatest kindness, and to-day this magnificent motor car is the outward and visible sign that I still retain your esteem, and that my humble efforts as a veterinary practitioner are appreciated. I feel that the agriculturists of Ross and Sutherland have put me under a debt of gratitude which can never be adequately repaid, but for the rest of my life it will always be my endeavour to uphold the honour of the veterinary profession, and if in my power to do more thorough service to you who honour me with your patronage. Reference has been made as to my qualifications, but, gentlemen, that was necessary in a district where farming is a science. The agriculturists of Ross and Sutherland have a knowledge of stock in health and disease that is not surpassed by any community in Britain. I must say that any success I may have had has been due to the wise and intelligent view which my clients invariably take of the ailments of the animals I am called upon to treat. I cannot very well thank you, gentlemen, without also thanking your good ladies for the many kindnesses and hospitality they have shown to me in the daily routine of my practice, the old proverb is true in my experience "that nowhere beats the heart so kindly as in the Highlands." Gentlemen, there is another thing that has made my work easier and that is the assistance rendered by the attendants of your stock. I must give the grieves, cattlemen, and ploughmen the greatest credit for their attention to a sick animal, and to carrying out instructions given. I have never found it otherwise than that these men have done everything in their power to assist in cases of illness, and do all they can to procure a recovery. You will, I know, accept this extremely imperfect acknowledgment of your kindness in the spirit in which it is tendered, being assured that I am unable to do justice to

such an event in vocal utterance. But, Mr. Chairman and gentlemen, you have laid upon me to-day another duty which I dare not evade. You have asked my wife to participate in your generosity in presenting her with this fine collection of silver. This, I can assure you, adds immeasurably to the pleasure which I feel on this occasion. Although she is not an expert in veterinary science, it is her lot to facilitate my work in many ways. To her I am indebted for all the comforts which take the rough edges off untimely hours, inclement weather, and irregular meals, and I am deeply grateful that you should honour her as well as myself. I can assure you that no one rejoices as much as Mrs. Brown at the distinction conferred on me to-day, and she desires me to express her heartfelt gratitude for the splendid presents you have asked me to accept on her behalf. (Loud applause.)

Mr. J. A. Forsyth, Balinaraid, said there had been a number of collectors working over a wide district, and those who had been called upon to give their mite could testify to the tactful manner in which they had been approached. (Applause.)

Mr. C. Mundell returned thanks on behalf of the collectors. Personally speaking, he had never had a more pleasant or more easy task. From the smallest crofter to the largest farmer he had no difficulty in getting contributions. He had only to ask to receive. (Applause.)

Mr. D. R. Cran, Ardmore, said this presentation had been an entire success, and that had been due in a large measure to Mr. Paterson, their chairman. He called for a hearty vote of thanks to Mr. Paterson. (Applause.)

Mr. Paterson returned thanks, and said that he particularly regretted the absence of Major Cuthbert, who had done so much towards the success of the movement. —*Ross-shire Journal*.

OBITUARY

ROBERT WILSON, M.R.C.V.S., China Street, Lancaster. Graduated, Lond: March, 1887.

Mr. Wilson died on April 21st, at Birmingham, from lobar pneumonia. Aged 50 years.

BURNDRED.—On April 23rd, at 148 Revidge Road, Blackburn, May Louisa, the dearly-loved wife of Ernest J. Burndred, M.R.C.V.S.

The late Mr. Henry Howse, M.R.C.V.S., of Lincoln.

Mr. Howse had reached the ripe old age of 80. Fifty years of that time he had spent in practice in Lincoln. He had an extensive high-class practice, his clients included some of the best known owners of horses in the country. He was a man of strong personality and could be trusted by his professional brethren; his skill and judgment were well known and were always in demand, not only among the rich, but among the poor, to whom no one acted with more generosity and kindness than Mr. Howse. Many and many a time he has attended horses belonging to small traders and others, knowing full well that he could never hope for anything like the usual payments, but he never refused to attend an animal in distress. Coming from London early in life, Mr. Howse spent some little time with his father at Norton Hall, and then came to Lincoln 50 years ago. His work for Lincoln Corporation was well known. He held the post of Veterinary Inspector for many years, and recently he was appointed consulting inspector to the same body. He was also Inspector for the Divisions of Lindsey and Kesteven some considerable time, and his work took him far afield. He leaves a large circle of friends to mourn his loss.

A memorial service was held at St. Peter-at-Arches Church, Lincoln, which the deceased attended for many years.

VOL. XXVI.

VETERINARY INSPECTION AND THE POLICE.

Mr. Brittlebank's paper on veterinary inspection, printed this week, is full of interesting points. Some of these—such as the old question of whole-time *versus* part-time inspectors—will cause some divergencies of opinion. Personally we think that the whole-time inspector has now become a necessity, and that Mr. Brittlebank's ideal scheme of "the establishment for every area of a fully equipped veterinary department which would deal with every animal disease which arises within its area, and responsible to the Board of Agriculture" will probably be realised ultimately. Upon another point mentioned by Mr. Brittlebank—the objections to the present predominance of the police in dealing with animal diseases—there will be no difference of opinion within the profession; and though it may be difficult to effect a reform in this direction, we do not think that an organised attempt would be altogether hopeless. Mr. Brittlebank spoke briefly, but very emphatically, of the harm wrought by police influence and police methods in dealing with animal disease. We doubt whether a single veterinary inspector of experience could be found to disagree with him.

In dealing with scheduled animal disease, there are two occasions on which police assistance becomes indispensable. One, of course, is when an owner is bent upon defying the law. The other is when some rapidly spreading epidemic, such as foot-and-mouth disease, necessitates stringent restrictions and extensive enquiries over large areas of ground, which could not be managed with sufficient speed without aid from the police. But both these cases are exceptional, and veterinary inspectors may be trusted to recognise the necessity for police aid when it arises. In ordinary circumstances—such as work under the Tuberculosis Order—the less the police have to do with the control of animal disease the better. Their presence and supervision do a great deal to prejudice owners against preventive legislation; their methods often do still more, while experience has shown that it is quite possible to administer such legislation effectively without them.

Of all scheduled diseases still remaining with us, we have made most headway against glanders. It is the one scheduled disease which we can confidently look forward to very soon exterminating. But in London—its home, our successful campaign against it has been, and is being carried on practically without aid from the police. If that can be done with glanders, it can be done also with tuberculosis and other diseases.

RADIAL PARALYSIS—A SEQUEL TO CASTING.

Subject, a seven-year-old cart mare, used by railway company for town work.

It was found necessary to cast her in order to remove a diseased molar tooth; this was difficult to extract, being the 6th, and having lifted it from socket the tooth shears divided it and removal was effected in two pieces.

On being allowed up, the near fore leg appeared useless, the elbow dropped, the leg was held forward in a bent position.

I have had cases of temporary paralysis which have disappeared after a little exercise, and I did not anticipate anything serious. The mare was taken back to stall with difficulty, and as no improvement took place in two days time, and the mare would not lie down, I put slings under her. She showed considerable pain as evidenced by sweating and inability to straighten the limb. At two weeks time the region around the elbow swelled considerably, and the triceps muscle was very tense.

Case looked somewhat alarming, and a second opinion was obtained. Fracture of humerus was suspected. When three weeks had passed, I had a message to say mare was standing on affected limb, and next day I took her out of slings and sent her out for walking exercise, which she did very well with exception of dragging toe a little. In three days time she was working quite sound.

Remarks. This case was no doubt due to animal resting on turf and being down rather a long time with head bent round, causing undue shoulder pressure on nerve plexus.

I have thought since, how the local bonesetter would have scored if he had been called in about third week.

A. J. CATTELL, M.R.C.V.S.

Brecon.

THE DESTRUCTION OF TUBERCULOUS VIRUS IN BYRES.

D. Ottoloughi and A. Londini have published (*La Clin. Vét.*) an article upon this subject. They have carried out experiments, planned so as to agree with natural conditions, and on the basis of their results they recommend a mixture of 1 per cent. corrosive sublimate with either 2.5 per cent. tartaric acid or 3.5 per cent. citric acid for the disinfection of byres which are contaminated with tuberculosis. Four to five litres (= about 7 to 8½ pints) of this fluid suffice to disinfect a square metre (= rather more than a square yard) of the surface

of the byre. Before using the disinfectant, the straw and dung are removed from the byre, and the ground of the byre is cleansed with water and a broom.

The acid in the disinfectant attacks the surrounding ammonia and salts of ammonia, the presence of which would otherwise weaken the disinfecting power of the sublimate. The sublimate attacks the surrounding sulphuretted hydrogen and its salts, and in doing so is naturally reduced. On that account the loss of sublimate must be provided for by using a highly concentrated solution. According to the authors' observations, if a 1 per cent. solution of sublimate is used, from 0.3 per cent. to 0.5 per cent. always remains in the solution without being lost in forming chemical combinations. This strength suffices to completely destroy tubercle bacilli, even in sputum and dried dung.

Compared with ordinary methods of disinfection, this one seems rather costly. But it is very speedy and certain, for within three hours tubercle bacilli mixed in moist or dry dung are rendered harmless, even when the ground to be disinfected consists of very porous material, such as bricks.

After the disinfection the whole of the byre should be thoroughly scrubbed and washed out with water, so as to remove all danger of mercurial poisoning to animals afterwards placed in it.—*Berliner Tier. Woch.*

A CASE OF SYMPTOMATIC URTICARIA IN A COW.

Neuenschwauder records (*Schweizer Archiv.*) the following observation, in which he was able to establish the etiology of a case of symptomatic urticaria.

He was called to a cow in which the presence of a foreign body in the œsophagus was suspected. The animal was protruding the tongue from the mouth, and was in a condition of intense dyspnea. The author immediately thought of anthrax, but as the temperature was 102° F., and the pulse 66, he abandoned this diagnosis. On examining the mouth he found a considerable œdematous engorgement of the frænum of the tongue, and of the buccal and pharyngeal mucous membranes. As these symptoms have been seldom reported in cases of urticaria, the author ascribed the condition to a sting from a bee or wasp, and advised that lukewarm milk only should be given, and that with great care.

At this moment the author learned that the cow had not been milked. He had already observed cases of urticaria in animals after the discontinuance of milking—generally after the second day—and therefore he examined further in this direction. He found that the udder was hard, the anus was engorged, and a number of œdematous places existed upon the shoulders. He therefore diagnosed urticaria. He had the cow milked out, and allowed her her liberty. The next day she had recovered.

The author thinks that the cause of the condition was the sudden discontinuance of milking. He considers that toxins, thus formed in the udder, were reabsorbed and exercised a deleterious action upon the organism.—*Annales de Méd. Vét.*

PERFORATION OF THE INTESTINE BY A FRAGMENT OF BONE IN THE DOG.

Rubay and Van Goidsenhoven record a case of this nature, and generally discuss the whole subject.

The bones which enter into the dog's diet are generally not large and are often spongy in texture, and are therefore broken up and reduced into very small fragments by the animal. According to their consistence and state of division, the duration of their stay in the stomach varies from a few hours to several days, or even longer. Reamur, after administering small bones (swallowed whole) to a dog, found that they were not dissolved after a stay of twenty-six hours in the stomach. They were, however, slightly decreased in volume and had become moderately flexible.

Attacked by a gastric juice which is normally rich in pepsin and hydrochloric acid, the particles of bone are completely disintegrated. The ossein is peptonised and the calcium phosphate is rendered soluble. The latter is precipitated in the alkaline contents of the intestine, and gives the excrements their well-known chalky aspect. In ordinary conditions these excrements are expelled from 24 to 48 hours after the ingestion of the bones.

In some cases, however, splinters of bone which are comparatively large and composed of very compact tissue, may find their way into the food and be swallowed whole. These are not easily acted upon by a normal gastric juice, and therefore their stay in the stomach may be a long one.

Spallanzani observed a case in which a dog retained bones in his stomach for seven days, after which period they had only sustained a distinct softening, and had diminished in weight.

These bones may occlude the pylorus, causing an obstruction. They may also pass the pylorus into the intestine, and, if small and regular in shape, be discharged with the feces. In other cases they may be arrested, in one part of the intestine, and act as foreign bodies. If a splinter, so arrested, is irregular in shape and presents sharp angles, it may perforate the intestinal wall and cause infectious peritonitis and rapid death.

The authors' case was one of a valuable pointer, three years old, which had died after a short and sudden illness, and was brought to them for post-mortem examination. On opening the abdomen, lesions of generalised infectious peritonitis were seen, with a sanious effusion of chocolate colour and repellent odour. This effusion filled the whole peritoneal cavity, and measured about two litres (= 3½ pints). The small intestine, about four-fifths of an inch from the termination of the ileum, showed a buttonhole-like orifice in which a fragment of bone was fixed. This orifice was about 1.15 inches long, had very clear cut edges, showed no trace of swelling or of hæmorrhagic infiltration, and simulated a lesion which had been caused after death. The piece of bone appeared to be a portion of an articular head, probably that of the humerus. In shape it was irregularly triangular, with sharp edges. It was about 1.1/6 inches high, and its base, which had not been able to pass the orifice,

measured 1-2/5 inches. Opposite to the first opening was another very small one, produced by an angle of the base of the osseous fragment. The digestive tube was completely empty, and the gastro-intestinal mucous membrane showed a diffuse inflammation.

The authors made an enquiry into the history and the preceding diet. The diet could be traced, and it appeared certain that the bone had formed part of a meal which had been given one evening. The next day defecation had been regular, but the dog had refused his ensuing meal. The day after that the back was arched, the animal would not even drink, and towards evening convulsions set in. These lasted some hours, and ended in coma and death.

From this observation the authors deduce a long series of conclusions, mostly repetitions of the views expressed in the early part of the article. They emphasise the fact that bones are not always so inoffensive an element in the dog's diet as some suppose. They explain the passage of so large a piece of bone through the pylorus by the fact that the animal's diet had largely consisted of bread. This undergoes little change in the stomach, and, if present there in quantity, forms a pulpy mass which may pass through the pylorus in large "waves," carrying with it a piece of bone. The end of the ileum, on account of the marked reduction in size which the intestine undergoes there, is the place at which bones and similar bodies are most frequently arrested, but arrestment and perforation may take place at any portion of the intestine. Finally, the illness following perforation may, as in the case above, run an extremely rapid course.—(*Annales de Méd. Vét.*)

NATIONAL VETERINARY MEDICAL ASSOCIATION.

A Council meeting was held at 10 Red Lion Square, on Thursday, March 12th, at 4 p.m. The Past-President (W. Woods, Esq.), in the chair. Present: Sir Stewart Stockman, Profs. Macqueen and Wooldridge, Messrs. Carter, Toope, Gooch, Samson, Hancock, and Harrison, Asist. Sec. Several letters regretting inability to attend were received.

The PAST-PRESIDENT rose and explained the reason he occupied the chair, and proposed that a vote of condolence be passed and recorded in the minutes expressing deep regret at the sad death of W. Hunting, Esq. and the great loss the Association and profession had sustained. The vote was passed, all present standing in silence.

The ASSISTANT SECRETARY read the notice of the meeting.

The minutes of the last Council meeting were read and confirmed.

SIR STEWART STOCKMAN (President of the Southern Branch) proposed that the date, time, and place of the annual general meeting be left to President, Treasurer, Assistant Secretary, and himself to arrange, suggesting a convenient date as some time during the International Congress, and place of meeting the Central Buildings, Westminster, S.W. This was carried.

The general feeling being that there was no occasion to provide any social function during the meeting. If any be held, to be self-supported.

It was proposed by Sir Stewart Stockman, seconded by Prof. Wooldridge, that it be a suggestion to the annual general meeting to hold the meeting in 1915 in Edinburgh.

Under the rules of the Association the Past-President and Assistant-Secretary agreed to continue in their respective offices until the next general meeting.

A letter was read from the Secretary of the Royal Sanitary Institute inviting the Association to appoint delegates to the Congress to be held in Blackpool from July 6th to 11th, and it was reported that Mr. W. Augustus Taylor, President of the Northern Branch, be invited to act as delegate from the N.V.M.A.

The Secretary was instructed to write Mr. Shipley, and say that his letter with reference to the appointment of a secretary with an honorarium was considered, and it was decided to defer taking any action to a future date, owing to the financial state of the Association.

The TREASURER made a short financial statement. There was a balance of about £60 at the beginning of last year, the amount in hand at present being between £20 and £30.

The Secretary was instructed to write Mr. Trevor Spencer in reply to his letter to the Treasurer, and say that it was placed before the meeting, and the Council accepted the affiliation of the National Association of Veterinary Inspectors to the Southern Branch on receipt of the necessary affiliation fee.

Mr. TOOPE read his progress report of Committee on insurance fees and scale of amended fees as finally adopted by the special committee. He drew attention to the difficulty experienced in getting replies from the various insurance companies.

After a full discussion in which the majority present took part, the action of the Sub-committee was supported by the Council, and Prof. Macqueen proposed, and Mr. Samson seconded, "that the scale of amended fees of the insurance societies, after the question of mileage has been settled by the Sub-committee, be submitted to the various societies for approval or otherwise."

On the suggestion of Mr. Toope it was agreed that the report be printed and attached to the minute book.

LANCASHIRE VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—NORTHERN BRANCH].

The quarterly meeting was held on Thursday, April 2nd, at the Grand Hotel, Manchester, the President G. H. Locke, Esq., in the chair. The attendance included Messrs. Woods, Ellis, Wolstenholme, Michaelis, Munro, Junr., Mattinson, E. J. Burndred, Walker, Holroyd, Whitehead, Stent, Heyes, Edwards, Richardson, Priestner, Holburn, and Brittlebank. Visitor: Mr. R. Finch.

Apologies for absence were received from Messrs. Abson, Lawson, Packman, Sumner, Darwell, Carter, Hughes, Wharam, and Garnett.

Minutes. Mr. Woods proposed and Mr. Wolstenholme seconded that the minutes of the last quarterly meeting be taken as read.

Correspondence. A letter dated March 28th from Mr. Wharam was read, suggesting that it would be a convenience to Yorkshire members if the meetings of the Association were held on Wednesday instead of Thursday. Further, that the word "Medical" should be deleted from the title of the Association.

Mr. WALKER proposed, and Mr. Mattinson seconded,

that Mr. Wharam's first suggestion should be referred to the Council for consideration and report.

With regard to the second suggestion, it was resolved to postpone consideration and to place the matter on the agenda for the next meeting. Proposed by Mr. Woods, seconded by Mr. Heyes.

Mr. GARNETT wrote on the question of the International Congress, hoping that the subscription list would be increased.

The PRESIDENT said it was very desirable that those who had not subscribed should endeavour to do so.

A letter was read from the Conjoint Veterinary Associations (Ireland), dated March 20th, calling the attention of members of the Lancashire V.M.A. to the fact that the veterinary practitioners of Ireland are desirous of having a direct representative on the Council of the R.C.V.S., and with that object in view have nominated Mr. P. J. Howard, M.R.C.V.S., of Ennis, for election. They invite support for Mr. Howard.

Mr. BRITTLEBANK pointed out that the Association was not actually asked to combine, and he thought the only course to pursue was to bring the letter to the notice of members. It was resolved that the Secretary be instructed to acknowledge the receipt of the letter and to intimate that the matter had been placed before the Association.

New Members. Mr. R. ISHERWOOD, Warrington, and Mr. C. W. ELAM, Liverpool, were unanimously elected members of the Association, being proposed by Mr. Noël Pillers, and seconded by Mr. Brittlebank.

Report of Council: Financial Position. Mr. BRITTLEBANK reminded the meeting that at the last quarterly meeting the question of the finances was discussed and referred to the Council for consideration. This had been done, and the Council recommend that each member attending the meetings of the Association and taking dinner be asked to contribute one shilling towards the cost.

Mr. WOLSTENHOLME proposed, and Mr. Mattinson seconded, that the recommendation of the Council be accepted.

Mr. BRITTLEBANK explained that the Council did not want to give up this social gathering. The Association is growing, and if it could be extended still further they would be more powerful. They did not want to put members to undue expense other than was actually necessary to carry on the work. The proposal was carried.

Professional Politics. The Council had discussed this matter and recommended that a small Sub-committee, not necessarily confined to members of the Council, should be appointed to watch the progress of events, and it was felt that the various Associations should exercise at the proper time more actual interest than they do.

Mr. BRITTLEBANK said the purpose of such a Committee was not very clear at present, but he felt that it was difficult for one man to watch entirely all the points that should be of interest from a political point of view to an Association such as theirs. His idea was to form a small Sub-committee entitled the Political Committee, the members of which would keep watch on matters arising in their own areas and from time to time such matters could be brought before the Association. It would be far better to thrash out these questions and take some joint line of action instead of acting independently according to one's own judgment, which may be formed without the possession of sufficient information. The constitution of the Committee is in the hands of the members, it should not be too centralised but fairly representative of the whole district. The question of professional education is becoming prominent, and it might be necessary for the committee to take this matter into consideration.

Mr. WOLSTENHOLME was of opinion that the whole Society should form the Committee. They met largely to talk about things connected with the politics of the profession. The matter touched each member and each should look out for events of vital interest to the profession. To pass this over to a sub-committee appeared to be delegating functions they ought to perform individually.

Mr. MATTINSON was in favour of every member taking a share in this matter, and thought they should be invited to bring cases of political interest before the Association just as they are now invited to bring other cases.

Mr. HEYES felt that each member ought to take an interest in veterinary politics, but how many set out specially to take such interest as to bring about or serve any useful purpose? He agreed with the idea of a sub-committee, and if the sub-committee could operate with committees of similar societies they would in course of time have a considerable influence. If they trusted to every member doing something they would not achieve anything more than had been done in the past. The Association only meets once a quarter, and there is barely time at present to discuss the various matters brought forward.

Mr. WOLSTENHOLME asked if the new National Association was not specially designed to meet positions of this kind.

Mr. BRITTLEBANK was entirely in accord with Mr. Wolstenholme that all members should feel sufficient interest in the profession to constitute themselves a political committee, but unfortunately experience of what is done is rather contrary to what people ought to do. Every man's job is no man's job, and unless you put special responsibilities on certain individuals you will seldom find anyone who will come forward and take initiative in ventilating matters of local interest. The right of a member who is not on the special committee to bring forward his political views at any time he wished would still be existent.

How far the functions of such a Committee can extend in the future he did not know, but his view was that they will become important. At present they will feel their way to see in which direction they could exercise their work. It was largely with a view to relieving the officers of the Association that he moved the proposition that such a Committee be formed, and that the matter be placed on the agenda for the next meeting.

Mr. MATTINSON seconded, and it was adopted.

Sanitary Institute Congress at Blackpool. The Council recommended the President be asked to represent the Association as delegate. Mr. Wolstenholme proposed, and Mr. Edwards seconded, that the recommendation be accepted. Carried.

TUBERCULOSIS ORDER, 1913.

By A. B. MATTINSON, F.R.C.V.S., D.V.S.M.

The following resolutions at a joint meeting of farmers and milk producers of the County of Cheshire are my excuse for troubling you with a few of my views on the Tuberculosis Order of 1913. This must not be considered to be an exhaustive paper on the subject, but merely in order to provide material for discussion.

I believe the members of our profession know much more on the subject than any other body, and I see no reason why we should not collectively voice our views for the guidance of the Board of Agriculture in any amendment of the Order which is contemplated, or about to be made.

"A joint meeting of the Councils of the Cheshire Milk Producers' Association and Cheshire Chamber of

Agriculture was held at Crewe on Feb. 16th, 1914, to consider what amendments are necessary to the Order. The following memorandum was agreed to:—

The Order has been in force about nine months, and is now admitted to be in some respects a failure. The causes of failure are:—

- (1) The complicated nature of its provisions.
- (2) The inadequate amount of compensation paid to stockowners.

The result of this is:—(a) Failure on the part of stockowners, and sometimes also on the part of officers of local authorities, to understand the provisions of the Order. (b) Widespread dissatisfaction with the amount of compensation paid.

The Order is consequently not fulfilling the purpose which, not only its promoters, but owners of stock had in view, viz., the elimination from the milk supply of those cows which are believed to be a danger and menace to the Public Health, and to pay to the owners of such cattle a fair and equitable value for them.

PROPOSED AMENDMENTS.

(1) **Valuation.** *One valuation only.* Before the slaughter of an animal the local authority shall either agree in writing with the owner of the animal the value thereof in the open market at the time of valuation, or if they shall fail so to agree the value shall be ascertained by a public valuer to be appointed by agreement between the local authority and the owner.

In the event of the local authority and the owner failing to agree as to the value of the animal, or if the owner refuses to accept the valuation of the public valuer appointed as aforesaid, the Board shall appoint a valuer whose decision shall be final.

(2) **Compensation.** *For Carcases.* (a) If the post-mortem examination proves the animal to be free from tuberculosis, the owner shall be paid by the local authority a sum equal to the full value of the animal as agreed upon, and a further sum of 20/-.

(b) If the post-mortem examination proves the animal to be affected with tuberculosis the owner to be paid three-fourths of the value of the animal as aforesaid.

For Milk. (c) Where a cow which has been examined under the provisions of the Order (Section 9) is subsequently found to be free from tuberculosis, and during the period the milk of such cow has been prohibited by the local authority from being sold or used for human food, the Local authority shall pay the owner for such milk for the period during which the examination and consequent prohibition has occurred.

(3) **Administration.** In view of the heavy cost of administering the Order, and the fact that this cost is incurred in the interest of Public Health, it seems right that at least one-half the cost of administration should be repaid to local authorities from the Imperial Exchequer.

JAMES SADLER, Secretary.

Crewe Gates, Crewe. Feb. 18, 1914."

With the bulk of these suggestions I entirely agree, except as regards (2) Compensation.

(a) I believe when the single valuation is adopted, that if the animal is free from tuberculosis the owner should receive £2 above the agreed value. This would rarely have to be paid, and when it had it is only right that the owner should be fully indemnified.

(b) With this suggestion I cannot agree for the following reasons:—Section 6 (2) of the Order says, "In ascertaining the value of an animal regard shall be had to any Act, Order, or Regulation dealing with the sale or use of milk, milk products, or carcases for human food."

This, to certain clients, entails much explanation and instruction as regards the Public Health and other Acts,

but it may be very concisely expressed as meaning—in the case of an affected animal—that if udder lesions are present the cow is valueless for dairy purposes and hence only for slaughter, and if emaciated she is also valueless except for slaughter and proper inspection of the carcase.

This again may be expressed by saying that all animals reported under the Order, and which the veterinary inspector is satisfied are affected, possess only one value, and that, *the carcase value after inspection and rejection of diseased parts*, and such being the case I suggest that as the proper basis of value.

The owner should in all cases receive the full salvage value, plus compensation; that the Treasury intended that more than bare salvage be paid is proved by the grant of £60,000 annually for compensation purposes, and an equal sum from local authorities.

I would suggest that the valuation should be full salvage value, plus compensation on a sliding scale, and tentatively put forward the following:

For carcases realising under £5, 12½% or 2s. 6d. per £ realised; minimum 30s.

For carcases realising from £5 to £10, 15% or 3s. per £ realised.

For carcases realising over £10, 20%, or 4s. per £ realised.

This would stimulate earlier reporting while the animals had a fair salvage value, and would thus remove animals before they got to the most infective stage of the disease, and good carcases with udder affection would be well paid for.

I cannot agree with the three-fourths or other fractional system of payment. If a cow is worth £12 and realises it, why should the owner only get £9. If, on the other hand, the cow is worth £9, why has the veterinary inspector to represent her as being worth £12, so that the owner may receive the bare value for her.

I may say here that I think it highly desirable that the owner should receive a copy of the valuation agreement at the time it is made; this is only an ordinary business proposition, and fair to both contracting parties.

To raise the highest possible salvage, local authorities should make proper arrangements for the slaughter of animals in places where the system of meat inspection is not too stringent. I am no advocate of "slink" traffic, but I do not think we should move too much in advance of public opinion, and, where the sale of such carcases is permitted after proper inspection, is the proper place to send affected animals.

It is essentially a very important part of the veterinary inspector's duty to see that the maximum salvage is realised, so that the Treasury grant and the local rates are not excessively drawn upon, and also to ensure that the farmer receives full value.

I should like to suggest here that the Board of Agriculture should definitely instruct the local authorities to pay over, in all cases, the full amount of salvage received, for at present that is not always the case. If a farmer receives less than the local authority get for a carcase he has a legitimate grievance, and such cases do lasting injury to the successful working of the Order.

Where carcases are dressed in the administrative county the veterinary inspector making the post-mortems should also be appointed as meat inspector to the County Council. At present the veterinary inspectors have no legal status as meat inspectors, and have no authority whatever to authorise or prevent the sale of a carcase for human food.

I should greatly prefer to use the term "marketable" for carcases in preference to "tuberculosis not being advanced, etc." as at present employed, on account of the great variation in methods and standards of meat inspection.

The term emaciation is synonymous with leanness or the state of being thin, and this is a very variable quality; an animal may be thin, *i.e.* emaciated, and yet quite valuable for slaughter if the lesions of disease are limited or absent.

Under the Order, however, Sec. 8, para. 4 (*d*) where there is emaciation and any lesions are present, it is *ipso facto*, advanced tuberculosis, although the carcass might be quite marketable and worth up to £8 or £10. The cutting down of such carcasses only tends to perpetuate the trafficking in "screw" cattle to country places where there is no supervision of the sink meat trade.

At first when the Order was put into operation I found that the police had arranged with local butchers in various districts to kill affected animals on the farms, for which they paid 15s. per head.

I had great misgivings that certain advanced cases were not being converted into "hen-meat" in spite of the earnest assurances of the butchers, and as I think slaughter at farms is always objectionable, I invariably have the animal removed.

Very emaciated cases I send to the knacker's at once, and others having a potential good value are sent to the public abattoir, where, if they prove to be unfit for food, the carcass is cremated and no question of "slinking" can occur. It is only placing temptation in the way of a butcher to allow animals to be slaughtered on farms, and to leave the removal of the carcass to the butcher for "hen-meat."

It would be well that the veterinary inspectors should be appointed by arrangement with the local authorities to carry out the provisions of the Dairies and Cowsheds Order, and thus help to forward the improvement in the sanitary conditions of buildings in which cattle are kept, as that is necessarily complementary to the Order if the maximum benefit is to be obtained.

May I briefly summarise what I believe are the most important points requiring amendment of the Order, or the instructions to local authorities, viz. :—

1. Simplification of valuation report; owner to be supplied with a copy of report.
2. Proper arrangements to realise the highest possible salvage after proper inspection of the carcasses.
3. Knacker, and not a butcher, to remove and slaughter very advanced cases.
4. Local authority not to make a profit on the salvage.
5. Occasional inspection of county sales, fairs, and farm-stock sales.
6. Efficient inspection of markets, cattle, and cowsheds.
7. Liberal compensation for the first few years to stimulate reporting and increase general information on the subject.

DISCUSSION.

Mr. ELLIS drew attention to the use of the word inspector, and thought the term veterinary inspector should always be used.

Mr. WHITEHEAD thought the Order was not carried out in different places as it ought to be. Where salvage has been more than the compensation it has been his plan to refer the people to the Section of the Diseases of Animals Act and tell them to fight the matter out. He thought the farmer was entitled to compensation after keeping back milk for three weeks. This point was dealt with in the Milk Bill which is in abeyance.

He agreed that all animals suffering from tuberculosis with emaciation should go to the knacker's yard. Those suffering from tuberculosis of the udder should be killed by a butcher, and the question of the disease being advanced or not advanced can then be dealt with.

The matter of some animals being worth more in certain towns than others raises the question of getting

a standard in meat inspection. The removal of suspected animals from markets should be stopped.

Mr. BURNEDD did not quite understand Mr. Mattinson when he said that in the case of an animal found to be free from tuberculosis, in addition to the compensation he would pay two pounds instead of one pound. He agreed with the valuation of an animal condemned with tuberculosis of the udder under the Dairies, Cowsheds and Milkshops Order, it should be valued as a beef animal; in this case he could not see why a bonus should be paid to the farmer over the amount. The same point could be met by saying his cow was worth dairy price. To his mind any cow affected with tuberculosis with emaciation is unfit for food, and any veterinary inspector who agrees to any salvage value is conniving with people who deal in such cattle.

Mr. HOLBURN said animal suffering from tuberculosis with emaciation, whether advanced or not, was certainly not fit for food. The one unfortunate thing in the Order to his mind is valuation. First they had to value an animal assuming it is not tuberculous, and if wrong, compensation has to be paid; then they had to value an animal as diseased. How could this be done? What valuation could be put on a tuberculous animal? In the other Acts an animal was valued at the price it was worth before becoming ill.

There is a want of uniformity of action between various county councils. Personally he was glad the Order had been introduced, but it required amendment. He desired to know how far an inspector was entitled to go when called to examine a cow. Should he inspect the rest of the herd? Form T4 has to be filled in and asks "Do you suspect other animals?" If you have not examined them how can you answer? The Cheshire County Council object to an inspection of other cattle, probably on the question of cost.

Mr. RICHARDSON instanced a case where he could not find any trace of tuberculosis in the milk, the cow was thin but not emaciated: she reacted, and his trouble was to value the animal knowing she was tuberculous, the lungs being undoubtedly affected. He valued her at £8, and got the owner to sign a form. On post-mortem she was extensively diseased. When the quarter's accounts were sent in he got a strong letter from the Board asking why he had classed the animal as emaciated; how was it that an emaciated case of tuberculosis which on post-mortem proved to be advanced could be worth £10? (The man only got £2 when he had finished). He had replied to the effect that according to the Order he had to value the animal whilst alive, and it was impossible to see inside until after death.

He also reported a case of advanced tuberculosis where the carcass being removed by a knacker was stated to be destined for the Halifax Zoo, but was found by a police sergeant being conveyed in an entirely different direction.

Mr. Woods agreed there was a certain amount of amendment of the Order necessary. It did not occur to him why a cow should be valued at more than full valuation plus £1, provided she turns out all right. Before suggesting any amendment they must be sure that county councils are carrying out the Act, because the farmer is entitled to the full value received by Act of Parliament. If that is not known it is not the fault of the Act. If the Lancashire County Council are making money out of the Order they have no right to do so, and the farmer can sue them and would get his money.

One point of the paper was of considerable value, and it all came to the question of compensation. It is not compensation to give a man less than he could make without the Act. Compensation must be dealt with in such a way that the farmer must receive more than he is receiving now. If the Act is to be effective they must

have the good-will of the farmer. He understood the Cheshire farmers had objected to two valuations, and it is perhaps somewhat difficult, but he believed a cow has two values.

He had a case now of a cow calved two months ago, giving 12-14 quarts of milk. He had found acid-fast bacilli, and the milk is being tested at the University. That cow has two values. If she has not tuberculosis of the udder she is worth about £20 as a milker, but if giving tuberculous milk she has no right to be used as a milker and is only fit for slaughter, and should be valued for beef; the latter value he fixed at £12. Any cases he had condemned for emaciation, if able to walk, had been sent to the knacker's yard, but they have been killed by a butcher so that if fit they could be passed for food.

Mr. BRITTLEBANK said he had listened carefully to the various speakers, and if confirmation was necessary it had been provided to-night by the discussion as to the necessity for a committee to look after professional politics. It would be recollected by some that for some time he had affirmed that the profession confined itself too much to itself, and if they wished to secure the authority which is theirs, or should be theirs, they would secure this only with the aid of the people they worked with, such as large agricultural societies, the Central Chamber of Agriculture, etc.

The whole point, to his mind, in the Tuberculosis Order—and he came into contact with it a good deal—is lack of uniformity in administration. Each county has its separate instructions to its veterinary inspectors, and these are often contrary to the spirit of the Order. The amendment should be one which would make it compulsory upon every County Council to carry out the provisions of the Order in the same manner and not interpret clauses in their own way. So far, experience under the Order has been mere experience, and one has gained a good deal of knowledge from its working. He thought ample knowledge had been gained to enable the Board of Agriculture to formulate sufficient amendments to make the working of the Order coincide with every county throughout the kingdom.

Speaking with regard to compensation, he was somewhat cynical. He had been looking back for a good many years at the general history of the payment of compensation for slaughter of animals, and there was no doubt the results were not good, and unless compensation was paid which would show a profit to the individuals concerned, the matter would always be a source of grievance. If you can go to the farmer and say you can give him a profit out of the transaction then you become his friend, and the Order would be a household word.

He disagreed with Mr. Woods about two valuations on a dairy animal, but thought a dairy animal in milk should be valued as a dairy cow, and compensation paid on that scale. It would be unfair to take the second valuation in the condition of that cow. You could take many other excellent milch cows which would approach a state of being valueless except as dairy cows—poor in condition chiefly, and probably due to the fact of the greater amount of work performed during lactation period. They should not be penalised by being valued as beef animals, it should be as working dairy cows. Compensation should be paid for milk from animals held up for examination, but where the cow is proved to be tuberculous, or in such a condition as to be unfit for human consumption, there should be no payment. Every County Council should arrange for condemned animals to be slaughtered at some recognised slaughter-house, and in no case should they be slaughtered at the farm. If the place for slaughter is some distance away, and the animal is incapable of walking, then the cow should be removed at the expense of the County Council.

The views of the agricultural community with regard to the apportionment of the cost of administration are just, and in place of the local authority having to bear the whole expense, the Imperial Exchequer should share it equally.

With regard to assessment of carcase for valuation, that is on post-mortem, under present conditions he was afraid, from his experience of a good many cattle slaughtered under this Order, that some veterinary surgeons have not interpreted the conditions which are laid down in Section 8 of the Order. These four recommendations were made by the Royal Commission on Tuberculosis with regard to the inspection of meat. They have been adopted by the Local Government Board and by the Board of Agriculture for the purpose of this Order and have been, he thought, interpreted in too severe a manner. Take for instance Sub-section B in this recommendation, "when tuberculous lesions are present on the pleura and peritoneum," but it does not follow that because the pleura is affected and not the peritoneum that the carcase should be condemned.

He remembered a case in which a big cow was affected with localised tuberculosis in both cavities, tuberculosis of the bronchial and mediastinal glands, also of the mesenteric glands, no tuberculosis of the serous membrane, and the inspector interpreted this as meaning tuberculosis of the advanced variety. The valuation was ridiculous—it was valued as worth £20. After he had agreed to assess her at three-quarter value the salvage to the farmer was only £3, and that was all he received for a time. Correspondence with the County Council ensued on the subject, and ultimately the farmer got the remaining £5 due to him as being the sum realised for the carcase. He felt sure from the words of the Minister for Agriculture that the method of valuation is going to be altered, and a system of single valuation adopted.

As time goes on, notification of suspected cases will disappear. What will develop will be responsible duties placed upon veterinary inspectors in various country districts in inspecting herds for local authorities who have received notification from Urban Councils saying that milk from a particular farm is tuberculous. That is the direction in which veterinary inspectors will have to expect the greatest amount of interest under the Order, and the clauses which govern that work should receive further consideration.

Mr. HEYES was of opinion that the Order has done good amongst the farmers. He had frequently been consulted as to whether an animal was tuberculous or not. He always examined the milk, and in that way had added to his knowledge as to the causal factor of many of the pathological conditions of the udders encountered. With respect to compensation, there must be a great difference of opinion unless some standard of what shall constitute advanced tuberculosis and otherwise is drawn up and acted upon.

Mr. MATTINSON replied to the discussion. He said the term "inspector" included veterinary inspector. With regard to all cases of tuberculosis with emaciation going to the knackers, he said this all centred on the question of emaciation. As to seeing the end of a carcase, they had nothing to do with it. If he thought they had a salvage value he sent them to the borough meat inspector, and if they were passed as fit for food well and good. In cases in the administrative county he (Mr. Mattinson) would take the responsibility himself. He was prepared to give liberal valuation, and did not believe in a fictitious value.

The various points mentioned in the discussion were dealt with.

Mr. BRITTLEBANK proposed a vote of thanks to Mr. Mattinson for his interesting paper. Mr. Richardson seconded, and the President supported.

The PRESIDENT stated that the Council recommended that the next quarterly meeting be held at Preston.

Mr. WOLSTENHOLME proposed this, Mr. Brittlebank seconded, and it was carried.

SEPTIC MENINGITIS, DUE TO INFECTION FROM PUS IN THE NASAL CAVITY OF A HORSE.

By J. B. WOLSTENHOLME, F.R.C.V.S.

On the 2nd February I admitted to hospital a grey cart gelding, about eight years old, with a temperature of 104°2', and some enlargement of the left submaxillary lymphatic gland: the case appeared as one of commencing strangles. The horse appeared to progress well for several days, the temperature on the 5th and 6th being 101°. On the morning of the 7th the temperature was 100°8', pulse normal. At 4 p.m. on this day the horse suddenly became dangerously ill, profuse sweating, both fore feet in the manger, the nose pointed upwards and pushed violently against the wall, the breast or neck, or nostrils, or shoulders, as it was most convenient for him to do. The respiration was very rapid and very laboured. At times he would attempt to climb the wall, it seemed that he could not stand without the support of the wall, he looked as though he would stagger and collapse and die immediately. At this time the pulse was 70, of medium strength, and the temperature 103°8'. The conjunctiva was not injected. At midnight he was a little easier, and stood without the support of the wall, but all four limbs were spread out, the horse had a curiously rigid appearance, and the nose was high up in the air. At this time he drank water.

He continued in this condition until he fell and died at 5 a.m. on the 8th. The nasal breath was very fetid on the 7th, but there was no discharge from the nostrils.

Post-mortem Examination. In the lungs there were a few small centres of commencing abscess formation, also some infarcts; the lungs were congested.

On opening the skull it was seen that the meninges were of a deep red colour from congested vessels. On removing the brain it was found that vessels were very engorged at the base, over the hemispheres, everywhere. There were small hæmorrhagic spots in places. After dividing the skull and face and removing the septum nasi it was seen that the antrum was of a dirty leaden colour, with here and there grey areas upon the thickened mucous membrane, each about the size of a lentil seed. The entire cavity was septic, with a very fetid odour, the inferior or posterior turbinate bone was filled with thick inspissated fetid pus, as also the inferior maxillary sinus.

On removing the plate of the superior maxillary bone, covering the fangs of the molar teeth, it was found that the purulent condition of the nasal cavity had had its origin from the fangs of the third and fourth molars, mainly that of the fourth, as the specimen will show. I had no knowledge of this condition when the horse entered hospital, but on enquiring was informed that the horse had had fetid breath for about two years.

The specimen shows a well developed seventh molar, between the tush and the first ordinary molar.

Mr. Wolstenholme was heartily thanked for his interesting communication and excellent specimen.

A vote of thanks to the President terminated the proceedings.

J. W. BRITTLEBANK, Hon. Sec.

The oldest English horse race is probably the contest originally styled the Kipling Annual Plate, which takes place according to precedent on the third Thursday of March, on the East Yorkshire wolds. Records prove that this quaint event, which is run along the turnpike road, has been run each year without a break for over two and a half centuries.

WESTERN COUNTIES
VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

CONTAGIOUS ABORTION*

(by Capt. HEAD, M.R.C.V.S., Helston.) DISCUSSION

The PRESIDENT (Mr. C. E. Perry): I am sure we have all listened with great pleasure to Capt. Head's very interesting paper. It is a subject that I personally do not know much about. I hope therefore we shall have a good discussion.

Mr. WM. ASCOTT: I should like to cordially thank Capt. Head for the very lucid manner in which he has placed this subject before us, and without attempting to discuss the paper, should like to ask, not only Capt. Head, but also the others present, their opinions as to when it is proper to remove the after-birth; some say it should be done at once, some on the third day, whilst others say not at all, but content themselves with drenching and syringing. I cannot help thinking that laziness, or at any rate a distaste of a dirty job, influences a good many of those who hold the latter view. In my experience it is astonishing what can be done with a little patience, especially if the uterus be first well irrigated with very hot water. I have found many an os, which at first appeared quite closed, suddenly dilate and allow the hand to be passed without difficulty into the uterus. The hot water also seems to have a considerable effect in separating the cotyledons, and I am strongly of opinion that the after-birth, or as much of it as can be got without injuring the cotyledons, is much better removed on or about the third day.

Mr. STABLEFORTH: I have had some experience of the working of the Abortion Order in Devon, and think it is doing a lot of good, but not as much as it would do if made universal. The number of cases have considerably lessened, there not having been so many re-occurrences this year as there were last. The penalty in cases where farmers substitute calves is not heavy enough, and judging from reports I have heard at markets, I should think quite 50 per cent. of the cases are not reported. The new Devon Order requiring antiseptic irrigation for seven days is a step in the right direction, but in many cases this period is insufficient to properly cleanse the animal. I should like to ask Capt. Head when he considers abortion most likely to occur. In my experience it is between seven and eight months. I always advise my clients to retain their own calves for the sake of the immunity they certainly possess.

Mr. LANSLEY: I have very little to say because I agree almost entirely with Capt. Head. I think legislation will do as much good as inoculation. I am certain the Devon side of my practice is now much freer from the disease than the Dorset side, which supports the argument for universal legislation. I find in many cases the farmer prefers to run the risk of the cow not cleansing properly rather than call in the veterinary surgeon and have the case reported as one of abortion. I have seen cases where abortion occurred the second time (the calf being carried a longer period than the first time), and the third time the cow has been rendered immune.

Mr. WHITEMORE: The Order not being in operation in my district, I do not know much about its working. With regard to the removal of the after-birth, I sometimes find it difficult to do this, as frequently one cannot get one's hand into the uterus. Does Capt. Head think the cow is clean after two months, and not

* See our issue of April 4th, p. 646.

capable of carrying infection? In my opinion it would be almost impossible in many cases to abstain from introducing fresh stock and at the same time successfully carry on business. I should also like to know how to test an aborted calf, which lived, to ascertain if it had acquired immunity. I should like to add my quota of thanks to Capt. Head for his admirable paper.

Mr. WM. PENHALE: I beg to thank Capt. Head for his very interesting paper; there is a lot in it and he must have had great experience in the subject. I, too, have had many cases of this disease in my practice. I think the Order is doing good, at any rate there is a great falling off in the number of cases reported, and I think the majority of them in my district are reported. I hope the Order will be continued, but I have reason to believe it is likely to be dropped; it will be a great pity if it is, as it undoubtedly prevents what used to be the common fraud of substitution. If cases are not reported, there should be a heavier fine; I have certain knowledge that the practice of substituting another calf and sending it with the aborted cow to market for sale, is very common. I do not believe in employing harsh measures with regard to the removal of the placental membranes, as I think it impossible to do so without injury to the cotyledons; rather than strip for it, which is necessary, I prefer to wait a day or two and try what good feeding and tonics will do. I should like to ask Capt. Head how long before inoculation should be tried? This is a very opportune time to bring forward such a paper. I learn Mr. Runciman is anxious that the Order should be made universal, but does not wish to unduly press the matter; whatever we can do to assist this object will be a great national service, for I am convinced the Order would be a great blessing if it were in vogue all over England.

Mr. JOHN DUNSTAN: There are two methods of testing, one is a serum used somewhat like tuberculin, and the other is the agglutination test. In this you draw blood from the suspected animal and send to the laboratory, where on analysis it can be ascertained if abortion will occur or not. The important point about testing is that it enables one to go into a herd and pick out and isolate the affected animals, and so prevent further infection from them. Our experiments with the agglutination test have been strikingly successful, we have treated one herd of over 1000, and the owner is delighted with the results. I am not in a position to quote the actual figures, but these will be published by Sir Stewart Stockman in due course. Personally, I have great faith in this test. One prominent symptom of the disease is that a cow will continually return to the bull but not get in calf. In what way is this connected with the disease? I shall be interested to hear if other members have had a similar experience of this. With regard to the time when abortion most commonly occurs, from experience I find it is about seven months, there being more cases at that period than all the others put together. We have it on the authority of the Royal Commission that immunity is conferred by continual abortion. I believe in removing the "after birth" on the third day whenever possible, but in some cases this is impossible.

I think we ought to discuss the advisability of continuing the Order in Devon, because Devon is being carefully watched by other counties, and an expression of opinion from such a meeting as this must be of considerable value. I am strongly of opinion that it would be a distinct advantage if the Order were extended to the whole of the British Isles. I, too, should like to add my thanks to Capt. Head for his paper.

Mr. R. E. L. PENHALE: I am fortunate in following two gentlemen who have had so much experience of epizootic abortion, and have given us their views thereon. I thank Capt. Head for his paper, which is so

practical and interesting. I don't believe the Devon County Council Order is much good at all, because it does not go to the root of the matter; one cannot tell with any degree of accuracy the result of the Order because the majority of the infected animals—I should think quite 90 per cent.—are being fed off; it is very difficult to induce farmers to keep them around. I cannot agree with such restrictions in buying and selling as are proposed, it would mean ruin to many a farmer and cause great stagnation in trade. My experience coincides with that of Mr. Dunstan when he states that seven months is the most prevalent period at which abortion takes place. Does Captain Head suggest it is possible to kill the bacilli with such a strength of antiseptic, which will not injure the mucous membrane of the womb? I find it is sometimes quite easy to remove the cleansing, while at others it is impossible.

Mr. P. PENHALE: This has been a most interesting paper. Before coming to the meeting I looked over the notes I made on this disease when at College and noticed that Professor Wooldridge stated that usually an aborted calf had no hair. I do not agree with those who say the bull is not a carrier of infection. My father considered solution of corrosive sublimate to be the best antiseptic for irrigating the uterus, but personally I have found considerable benefit from the use of very hot water, as hot as can be borne. I have treated three herds with what is known as the carbolic treatment, with a fair amount of success.

Mr. DOWN: I beg to thank Capt. Head. I have listened with much interest to his paper, and also to the remarks of other speakers. The ground has been so well covered there is not much left for me to say. With regard to the removal of the cleansing, I do not believe in meddling too quickly with the cotyledons for fear of injury, but get it away if you can. I was recently called to a cow which had twins; the farmer said, "Don't remove the cleansing," so I washed her out and left her. The next day the cleansing was further out, but the owner still refused to have it taken off, so I washed her out again. The third day she was ill with every symptom of blood poisoning, so the owner then consented to have the cleansing removed, after which she rapidly got better.

Mr. THORBURN: I have very little to add except my thanks to Capt. Head. I think it would be a very great pity if the Order were dropped. I have never seen so much abortion anywhere as in my district (Somerset) where the Order is not in force. Just a word about removing the cleansing. I think it a great mistake to inject antiseptics at all, as in my opinion this retards the separation of the cleansing from the cotyledons. I use boiled warm water only. I am glad to hear Capt. Head is so optimistic about the ease of stamping out the disease, because it will not only be a great blessing to the country, but a credit to our profession.

Mr. BOND: I am delighted we were so fortunate as to get Capt. Head to give us this paper, it has come just at the right time. You will probably remember Prof. Axe gave us a paper at Tavistock on the same subject some years ago, but very little came of it. I had an interesting and somewhat amusing experience some little time ago. I was called to a cow said to have aborted, took smears, and as a result reported it to be contagious. The owner was dissatisfied, so we consulted Sir John M'Fadyean, who suggested applying the agglutination test; the result being positive. The owner then wished to have the remainder of his cows, 11 in number, tested. Two of these were said to be affected, and the other nine free. One of the two has gone her full time and produced a live calf, and the other is shortly likely to, while four of those said to be free have aborted. The knowledge that cows acquire

immunity is very valuable, and will be the means of saving thousands being fed off. I think cows should be kept four months before being put to the bull again.

Mr. BLOYE: I should like to ask Capt. Head on what authority he bases his statement that male and virgin animals are immune against this disease.

Mr. GIBBINGS: I do not agree with Capt. Head as to the ease of diagnosing contagious abortion with the aid of the microscope. It is not always easy to differentiate groups of staphylococci from Bang's bacillus; there are numbers of cases of contagious abortion where one cannot find the bacilli, and if you rely on microscopical examination only you may be led to erroneous conclusions. I think it is equally criminal to sell in-calf cows from an infected farm as to sell aborted cows with substituted calves, and legislation in this direction is necessary. I am one of those who believe it is impossible to kill the germs in the uterus by antiseptic injections. One would need to keep a pump going with a 5 per cent. solution all day. I hold it is impossible in a great number of cases to remove the cleansing without incurring the risk of serious injury to the cow.

REPLY.

Capt. HEAD: I think as a profession we, like medical men, jump from one extreme to the other, as witness our views with regard to antiseptics; we must remember that antiseptics do not kill germs, but prevent their growth. Hot water injections are quite good, and it is surprising what a lot of it the womb will stand. If the placenta is going to be taken away, and I think it should be, it is best done within three days as after that the os contracts and renders the operation more difficult. Replying to Mr. Bloye, I stated on the authority of Sir John McFadyean and Sir Stewart Stockman that the bacillus has never been found in the male or the virgin, the uterus being the only place in which it will grow. I do not see why abortion should take place at the second and not at the first calving. Personally I have found as much trouble with heifers as with cows. The period of two months for cleansing is based on the results of inoculation in which it has been proved to answer. The age for inoculation depends on when the animals are to be put to the bull, when that has been decided they should be inoculated two months beforehand. I do not know if calves from aborted calves acquire a life-long immunity, as I have not had time to prove it, but as far as I have come I have reason to believe it to be so. I cannot quite agree with some as to the value of the agglutination test, because I do not see what good it is to know which are and which are not going to abort, for if you take those that are affected out, the others may still pick up the disease from the same source as before.

I thank you, gentlemen, for the kind attention you have given me.

A hearty vote of thanks to Capt. Head, proposed from the chair, was carried with acclamation.

Mr. BLOYE: I claim it my privilege to move a cordial vote of thanks to my old friend Mr. Perry. It was my pleasure twelve months ago to propose him as our President, and I now have equal pleasure in testifying that he has, during his term of office, gone out of his way to be of more than ordinary service to the Association. This was seconded by Mr. R. E. L. Penhale, and unanimously carried.

On the motion of Mr. Thorburn, seconded by Mr. Roach, it was resolved to convey a vote of condolence to Mr. W. B. Nelder, of Exeter, on the death of his daughter.

WM. ASCOTT, Hon. Sec.

NORTH MIDLAND VETERINARY ASSOCIATION

[NATIONAL V.M.A.—NORTHERN BRANCH].

The quarterly meeting was held at the Grand Hotel, Sheffield, on April 21st. Present:—Messrs. F. L. Somerset, in the chair; J. S. Lloyd, Hon. Sec.; H. Thompson, Hon. Treasurer; G. Howe, W. Collinson, C. Secker Smith, S. H. Nixon, Bruce Selous, M. Robinson, W. Brown, G. J. Furness, H. P. Lewis, J. Abson, T. C. Fletcher, E. G. Johnson, G. Green, S. E. Sampson, W. Murgatroyd, R. Hudson, H. R. Laycock, and H. W. Dawes, jun.,

Visitors:—Messrs. J. W. Brittlebank, J. Pollard, J. D. Whitehead, and C. Pitts.

The minutes of the last quarterly meeting were read and confirmed, on the proposition of Mr. Robinson, seconded by Mr. Collinson.

The report of the Council meeting held on April 7th was read.

Hunting Petition. The President was authorised to sign the petition on behalf of the members.

A letter was read from Miss Louie Hunting thanking the Association for their resolution of sympathy.

Hunting Memorial Fund. Proposed by Mr. Smith, seconded by Mr. Thompson, that the matter be again deferred to the next quarterly meeting.

Other Correspondence. A letter was read from Mr. E. C. Winter soliciting the votes of the members on behalf of Mr. P. J. Howard, M.R.C.V.S., of Ennis, who is standing as a candidate for a seat on the Council of the Royal College of Veterinary Surgeons at the election in May next.

The PRESIDENT expressed the opinion that it is desirable that the Irish practitioners should have direct representation on the Council of the College, but that it should be left to individual members to vote as they wished.

Exco to Essayists. It was proposed by Mr. Furness, seconded by Mr. S. H. Nixon, that the sum of £1 1s. be allowed to essayists who come from a distance.

New Members. Mr. PERCY HOYLAND, of Rotherham, on the proposition of Mr. Collinson, seconded by Mr. Green, was nominated as a member of the Association.

Mr. W. WADSWORTH, M.R.C.V.S., of Sheffield, was elected a member of the Association.

Instruments. The question of the purchase and loan of instruments by the Association was discussed. The President suggested that the members should prepare a list of instruments which they do not possess and which they would like to use, and also a list of instruments which they have and which they are prepared to lend to other members of the Association.

Microscopist. Mr. T. C. FLETCHER proposed that a member of the Association should be appointed to act as honorary microscopist. He said, "we have a gentleman amongst us who is extremely intimate and clever with the use of the microscope, and as we are not all intimate and clever I think it would be advisable that, he being willing, specimens were sent him for examination. I will just enumerate a few. Perhaps first and foremost would be milk for the presence of tubercle bacilli, scrapings for parasitic mange, condition of certain forms of tumours from the dog, etc., and perhaps blood of anthrax, and several others, a list of which would want making out. Having a gentleman who seems willing to accept the post has eased my duties a good deal in bringing the matter before the Association, I do not see how any member of this Association can fall out with this idea, because I take it that if he does he is either very clever or does not want any help. If it meets your pleasure I should be very

pleased to ask Mr. H. P. Lewis, who I have in mind, to undertake the post. The details will want working out. I think the proper mode of procedure would be to ask Mr. Lewis to submit suggested regulations to the members.

THE PRESIDENT: The appointment would no doubt be very useful. The question is whether Mr. Lewis would undertake the work. No doubt he will tell you if he does accept that certain precautions will have to be taken in sending specimens, but he will probably give some sort of regulations as to the manner in which specimens should be sent. I have great pleasure in seconding the proposition and asking Mr. Lewis to take the office.

MR. H. P. LEWIS: I shall be extremely pleased to do anything I can. Anything I do will be for the benefit of the profession, and the members of this Association more particularly. I hope the members will look upon the position as purely an honorary one. I am much obliged for the honour you have done me in asking me to accept the position.

VETERINARY INSPECTION IN RELATION TO THE PUBLIC HEALTH SERVICE.

By J. W. BRITTLEBANK, M.R.C.V.S.
Veterinary Inspector City of Manchester.

I little suspected when I took up the invitation extended to me by Mr. Lloyd, and which naturally I highly appreciate, what a large and controversial subject I was entering upon.

To one who loves his profession, and has watched with interest the progress in scientific work made by the profession during the past twenty years, the first thought which occurs—how marked are the changes which are coming or have come in the professional existence of many of us, and the changes in this short period of years, which is really infinitesimal in the history of a profession, are most remarkable.

If you will forgive my being reminiscent and tempted to look back to the time when I joined the New Veterinary College, a student under that grand old man, Principal Williams, the prospects before those of us who were proceeding to obtain our diploma were practically limited to the choice of either general practice or attempting to enter the Army Veterinary Department, as it was then called. True, here and there a stray sheep from the better disciplined or more respectable flock might be found engaged in the municipal service—the work being confined principally to that of meat inspection. I say further, without fear of contradiction, that such gentlemen were regarded by their more fortunate professional brethren with ill-concealed contempt, and one frequently heard such an one referred to as occupying a suitable job “as he would never have done any good in practice”—that great and never failing test of a man's scientific attainments and work as a veterinarian. It was not to be presumed for a moment that it was necessary for any individual occupying such a position as a public official to have any special qualifications above the ordinary; it was, in fact, a “soft job.”

What is the change that this pioneer work of these ill-paid public servants has brought about for our profession to-day? Motor traction is displacing our equine friends in greatly increasing numbers year by year, and the pessimist tells us the days of the veterinarian are numbered, and that in a few generations the only evidence of his existence may be obtainable in the British Museum or other such collections which record the existence of bodies which are past. Personally, I have no place for pessimists; many of them have done well financially, are content to sit in their clubs and croak of the days that are gone and the fees that are no more, but would do little to help the pro-

fession to maintain its entity and secure its position in the van of progress. That such individuals are not too numerous in our profession is something to be thankful for; they are of no use to any but themselves.

I may be an optimist, but how many are there who will deny on reasonable grounds that there are avenues open and opening for the members of our profession which will provide employment ultimately for far more than are available were such openings to present themselves to-day—else why was the Select Committee appointed, under the chairmanship of Sir Alfred Hopkinson, to consider veterinary education and the provision of veterinarians for the public services? It will, however, depend largely upon our own capacity for statesmanship if we are to develop, and to secure the positions which will be ours by right.

What is the position of the veterinary public officer to-day, thanks to the unflinching efforts of those pioneers I have referred to? True, he is still ill-paid, and often occupies a subsidiary position, but he has progressed to the extent that he is admitted by his brethren, the general practitioners, to be on an equality, and has justified his existence, and is none the less a veterinary surgeon.

The public health veterinary surgeon occupies a somewhat curious position; he is engaged chiefly in the supervision of our food supplies, is principally occupied in the examination of meat and the inspection of dairy cattle, but for all that has very little legal standing. I need not enlarge upon this point, but would refer you to a very excellent paper read before the Lancashire Veterinary Medical Association at the December meeting by Mr. Whitehead, the veterinary officer to the Salford Corporation. As I have stated, the duties officially recognised are very circumscribed, but a veterinary officer is frequently called upon to exercise his activities in many other directions than those just referred to.

Of recent years much has been written and said about veterinary education, and I don't propose to refer to it at any length to-night, but it would perhaps not be out of place to inquire whether the veterinary education of to-day is calculated to suitably equip men to occupy the public positions which are opening. The principals of our veterinary colleges have almost unanimously said that the education provided is ample for any purpose. That is final, and should be sufficient, despite the contrary experience of many of us who occupy these positions.

With the curriculum of the veterinary student I have little fault to find; one might be tempted to criticise the methods employed for training, but with this I am little concerned for the present. This much I will say, and I have many opportunities for forming the opinions I express—that there is a great amount of excellent material coming through our colleges, many men who show great promise; but, without wishing to be dogmatic or egotistical, I still repeat that to make efficient public officials they require further training, and I certainly think this should be post graduate, and should not follow immediately upon obtaining the membership diploma.

Some of you may recollect that at the last meeting of the National Association Mr. Henry Gray read a paper entitled “Do we need a new Degree?” The principal object of this paper appeared to be an attack on those of us who had thought fit to obtain the necessary post-graduate training in one or other of our Universities, to exhibit an entire and lamentable ignorance of the nature of the duties we are likely to be called upon to perform, and to finish up with the brilliant conclusion that to carry out the work of a public health veterinary officer it is not at all necessary to be trained as a veterinary surgeon, but that a short course entitling one to emerge with the full glory of the title of veterinary sanitary

inspector was all that was required. A truly progressive proposition. Yet nobody has disputed the fact that it is necessary to have fully trained veterinary surgeons to attend to common ailments of canine and feline pets.

Fortunately the Royal College of Veterinary Surgeons has replied to this by deciding to establish a post-graduate degree to be entitled the Diploma in Veterinary State Medicine, and even if the decision has been arrived at late in the day, we must be thankful for small mercies. I do not really blame the Council of the Royal College for being dilatory. The lack of money, from which they suffer, is always bound to stand in the way of progress, but one may express a hope that nothing will be done to restrict the facilities for securing the necessary training. Many young veterinary surgeons cannot afford the time and money necessary if they have to give up their posts and proceed to one or other of the veterinary schools. Ample facilities are provided by most of the provincial Universities, and all that is required is for a student to attend an approved course and then be allowed to sit for the diploma granted by the Royal College of Veterinary Surgeons.

As I said earlier, the chief duties which veterinary surgeons are called upon to perform as public officers are the inspection and examination of foodstuffs and their sources. The inspector is usually attached to either a public health department or markets department, but it is immaterial which, he is none the less a public health official. In the first case he works under the direction of the medical officer of health, and where he is part of the staff of a markets department is under a lay superintendent. It will therefore be clear that for the present he is not chief of a department, but is responsible to an official higher placed than himself.

Much has been said from time to time of this condition of affairs, but for the most part it is a variety of vain howling at our lot, with little prospect of escape to more independent surroundings. Naturally, every self-reliant veterinary surgeon who is not afraid of responsibility objects to supervision by people who little understand the nature of the work he may be called upon to perform; but shall we gain anything by abusing these people, and by recording instances of their follies? I venture to think not. We are, as a profession, numerically small; the medical officers of health hold the fort, and the prospects of successful assault are infinitesimal.

It is, for instance, provided even in the Milk Clause that a "medical officer may, if accompanied by a veterinary surgeon, at all reasonable hours enter the dairy and inspect the cows kept therein"—a truly Gilbertian situation, which does not even indicate that the veterinary surgeon is to examine the cows, but that the veterinarian may wander about under the fostering care of that highly intelligent and impressively superior being the average medical officer of health.

Certainly the Parliamentary Committee of the Royal College of Veterinary Surgeons were successful in obtaining an improved amendment of this Clause—but why, in the name of fortune or common sense, is it necessary for the medical officer to be there at all? By far the greater number of them—I am not exaggerating when I say 99 per cent.—know as much about cattle as I do about higher theology, and that is precious little; but for the time being such is the law, and we must abide by it.

I do not suggest that we should separate from the medical profession—indeed, to my mind this would be a retrograde step, and for my part whatever the conditions, I would rather work under a professional man than a layman. The scientific difficulties one has to contend with will be more apparent to the former, while to the latter the business aspects of any problem will remain paramount. I think the proper method of procedure is for the profession to secure in all Parlia-

mentary Bills a clear and definite position for the veterinary officer, a position which will place him as his professional qualifications entitle him to be placed. Young veterinary surgeons should secure as many of the appointments as possible, never minding the position of affairs as they stand to-day; then when we are numerically strong enough to have an efficient combination, we shall be able to force the hands of the authorities and compel them to place them on a proper footing.

It must be remembered that general abuse of the medical officer has two effects—(1) To restrain him from recommending the appointment of veterinary officers; (2) that in many cases where such are appointed it does not help to improve their position. Instead, let us have something constructive, something definite to work for; we are all desirous of obtaining the same end, and it therefore becomes a question as to which is the soundest policy.

The question of veterinary meat inspection is one that requires urgent attention. It cannot be insisted upon too strongly that the proper man for this position is the veterinary surgeon. I do not object to lay assistance where necessary, but the controlling head should be a veterinary surgeon.

The next question is: Has scientific meat inspection progressed as it ought during the past few years? I think that on the whole the question may be answered in the affirmative. It must be remembered that the opportunities for proper scientific work are limited. A large number of private slaughter-houses still exist, and until they are abolished and a proper system established in public abattoirs progress will be slow.

Many municipal abattoirs exist—there are few, however, in this country which would comply with modern requirements. For instance, how many are equipped with properly furnished bacteriological laboratories? The paucity of such establishments is evidenced by the almost entire absence from our professional journals of any work notes in a post-mortem field of such immense and unlimited extent. It may be said that the veterinarians engaged in meat inspection are too busy to do any research work, and this may be true, but as a rule an enthusiast will find the necessary time if he wishes to.

There should be a uniform standard of compulsory meat inspection throughout the country—at present the traders of one community are penalised while others go scot-free, and both may be found making their purchases in the same live market.

The qualifications of a veterinary surgeon do not entitle him to act legally as a meat inspector, and it is necessary for him to be appointed an inspector of nuisances before he can seize unwholesome food. This requires drastic amendment at the very first opportunity.

It is of little use entering too deeply into details, but the sphere of activities of the public health veterinary officer is unlimited. He should be the veterinary officer of health in reality, and the conditions appertaining to the health and housing of all animals in his area should be his special care.

There may be some little objection to the use of the title of Veterinary Officer of Health. It is adopted I know fairly commonly, and for lack of something better. I presume it denotes the position of such official, but for my own part I do not care much about it as I do not wish it to appear that we are copying our medical *contrères* or rather attempting to bask in a cheap imitation of their titles. What is it that is required to obtain this efficient control? First of all we require new legislation. If you will think of the legislation which we possess to-day and the powers under which we act generally you will find that they are built up principally in a "hodge-podge" sort of way by a number of

Orders which are made under old-existing Acts, and it will be practically impossible in my opinion for the veterinary surgeon of to-day to make very much progress until the whole legal aspect of the question is reconsidered. This affects the practitioner quite as much as the whole-time officer.

I may here refer to this question. I know that to many the term "whole-time officer" is a sort of bug-bear, but I think that the time is rapidly coming when the profession should look at these things from a broader point of view. The whole-time officer has come to stay. He has in his hands a good deal of authority, and I cannot for the life of me see him doing his professional brother in practice the slightest harm. If you look back to the history of the medical profession, with whom I think we are distinctly comparable, and on whose lines we might safely follow if we wish to put ourselves where we ought to be, we shall see that the medical profession is perhaps to-day in a more prosperous position than it ever was. To obtain this position (of course that celebrated statesman, who is much abused and much praised in certain quarters has undoubtedly assisted in no small degree), the first step which was taken was the passing of the Infectious Diseases Notification Act. When that Act was passed it made the notification of infectious disease compulsory alike upon the parent as upon the medical attendant. Following that a little later the medical attendant was paid for the notification which he made, and following that again came the necessity of having an official to receive these notifications, and to deal with the preventive measures which were necessary under the Public Health Acts which were in existence.

The veterinary profession to-day, perhaps not quite so much as in the past, seems to object to be required to notify disease. There is much to be said on both sides, but I think in the long run that if the veterinary attendant were required to notify and were paid for his notification of contagious diseases, and if a proper system of notification were established, then it would not be long before the owners of animals would get quite as used to it as the human patients have got with the system to-day. Until such system is brought about there can be no efficient control of disease in this country. The next step would be the appointment of public veterinary officers generally throughout the country. What would be the effect of this? Would it take work out of the hands of the practitioner? My personal conviction is that it would never do so, because a man's time—those of us who are already public officials know it—is fully occupied with carrying out administrative work without trying to collar anything in the way of another man's living.

The present position of affairs is about as clumsy as it is possible to imagine. The whole control of animal diseases is centralised. The essential requirements to properly control any area are that a man shall know the area with which he has to deal, and that he shall be personally known to a very large number of the people with whom he has to deal. To-day you find that various diseases are notifiable and administered from various quarters. I need not refer to them—most of you know them perfectly well—but if we have a scare that there is an outbreak of foot-and-mouth disease, the local veterinary officer is regarded as incapable of dealing with it, and it is necessary to send a notification to the Central Authority and they come down to deal with the matter themselves. The system that is at work to-day may be a necessity, but it is not the system that one would like to see existing. The ideal would be the establishment for every area of a fully equipped veterinary department which would deal with every animal disease which arises within its area, and responsible to the Board of Agriculture, and to do this successfully the whole profession would have to form part of this

service—as in the medical profession, but unfortunately there seems very little prospect of these steps being taken. We have to go along working under these patch-work orders, and the position of the veterinarian will remain very largely what it is. In odd cases it will be found possible to obtain a greater amount of control and to improve the conditions, but the general conditions will remain, and I therefore strongly think that the profession requires to recommend fresh legislation to take the place of the obsolete legislation under which we work to-day, and then be all prepared to follow what might be called the trade union methods of the British Medical Association when we are sufficiently combined. I do not see why our profession should not become as combined as the medical profession, and then be able to obtain the positions that are its right.

There is one matter in dealing with the questions of legislation which I think might be proposed—that as far as possible the whole of the administrative powers should be placed in the hands of the veterinary profession. At present the police are the predominant parties. They are useful in their proper place, but in my opinion when police methods are pre-eminent the notification of disease becomes practically a dead letter, and the veterinary inspector himself shows a tendency to assume a sort of police attitude; thus the whole procedure is calculated to breed resentment.

Another illustration which we have to-day in the piece of legislation which is the last one passed—the Tuberculosis Order. If I were asked to say what was the stumbling block in the way of that Order I would undoubtedly say the influence of the police. I have seen a good deal of it. Those people who are required to notify disease, and the veterinary surgeons in practice who are required to notify, are in much the same position. These people have done no crime, and yet when the policeman gets on the premises the man is treated very much as if he had committed a crime until the unfortunate animal or animals are destroyed. My firm conviction is that that is one of the reasons why the Tuberculosis Order is not working as smoothly as the veterinary officers of the Board would wish it to do. If the veterinary officers of the Board and local veterinary officers were to carry out this Order themselves, and to carry out the administrative measures necessary as they strike the man on the spot, without a lot of red tape, irrespective of the grumbling as to the scale of compensation, I believe a tremendous amount would be made out of this Order.

There are no possible means of finding out to-day the number of cases which arise in country districts. Many of the conditions which are of vital interest to farmers are never mentioned. I was speaking a little while ago to a big farmer who had a very serious outbreak amongst his ewes, and I advised him to notify to Sir Stewart Stockman and see what he could do. His reply was "I do not object to the veterinary inspector of the Board if he would only come here without the policeman and the lay inspector," and I think he was nearly right.

The next question which arises is—How is this profession and its members to obtain its proper place irrespective of the legislation which I have mentioned. I think we have been too much inclined to plough this lonely furrow on our own. We have stood on our dignity, and have been perfectly satisfied to go on fighting this uphill battle alone. We have made progress, but it is a question if we have made the progress we ought. I think if our profession were to make overtures not to another profession who only patronise us, but to the large agricultural interests in this country, and could get their backing, we should very soon secure what we want, or at any rate a certain measure of it. I mean large national bodies like the Royal Agricultural Society of England and the Central Chamber of Agri-

culture. These people are brought daily into intimate contact with us. They know that to a very large extent the health of their stocks and the prosperity of their business so far as their stocks are concerned are in our hands, and I do not think it would take very much to make these people take up our case. It is quite useless for a small profession like ours to remain by themselves. I do not know exactly how many veterinary surgeons there are in this country, probably not many more than 2000 in active practice, and what do they represent?—a very small money capital. That is the way the Government are apt to look on things. What is the capital in the body, and what is their voting power? As a voting power we are only scattered units, and we have, most of us, only one vote each; while we are so situated we are helpless. Go to the industry in which we are interested. We form part and parcel of that industry, get their backing, and I feel sure that it would not take very long to get those amendments to Acts which are our right. Those Public Health Acts Amendments which say that the medical officer of health, if accompanied by a veterinary officer, may at any hour examine the cattle are an insult to our profession. I note the Parliamentary Committee have got the stipulation that the veterinary surgeon shall examine the cows, but he has still to have his medical officer with him. I do not want to labour this question. I have treated it in a very sketchy sort of way. I did not want to read a lot of Acts and Orders, but there is one thing that I do ask for—that is if our profession is to continue to exist, there must be no jealousies with regard to public officials. In the district in which I work, and I am sure Mr. Lloyd will have experienced the same, we receive nothing but kindness from the men in practice. In making the remarks about medical officers I do not make them from my own point of view, I make them from the standpoint of other men. My own medical officer is one of the strongest advocates for a public veterinary service that we can possibly have. I am responsible for all the administration, but he has a perfect right to discuss details, and discuss them he does. He leaves everything to me, but the fact remains that if he likes to exercise his right he can place me in the position of an inferior sanitary inspector, and make me realise that I am some sort of a worm that is ready to be trodden on at any hour.

DISCUSSION.

The PRESIDENT: Our first duty will be to acknowledge with gratitude the kindness of our friend Mr. Brittlebank in coming down and giving us this address. He is well qualified to give an address on this subject as you are all well aware. There are one or two gentlemen present who occupy positions somewhat similar to that of Mr. Brittlebank, and who no doubt will have something to say on this particular question. Others of us are sort of half-and-half men, who are not whole-time men, but who have appointments which one might describe as appointments under Public Health, such as dealing with animals under the Tuberculosis Order, and as Board of Agriculture Inspectors as well. Those of us who have these positions will have noticed the disposition of the Central Authority to take over the administration of the various Orders which come under the Act. They started with swine fever, and they have not made a very sound job of that, and now they take foot-and-mouth, and now anthrax, which was formerly left in the hands of the local authority. The local veterinary inspector has to send specimens to the veterinary inspector of the Board. Perhaps some of you would notice in one of the periodicals some time ago that cases had not been confirmed by the Central Authority which there was very good reason to believe should have been confirmed. My own experience is that they are quite as capable of making mistakes as anyone else. There

are cases which have not been confirmed which should have been, and it is annoying for the local veterinary inspector to have that slur cast on his diagnostic abilities; but at present there is no redress, and if they say it is not a case it is not a case, and you must put up with it.

As to the lines we should adopt in order to get greater recognition, Mr. Brittlebank recommends that we should appeal to the agriculturist. Well, the agriculturists are, as a rule, men with a keen eye on the rates, and the increase of officials is a thing which they are very much opposed to. The idea of appealing to them to vote for the establishment of Veterinary Departments which involve an increase in the rates would not meet with much success.

I quite agree with Mr. Brittlebank on one point—that a stumbling block in the proper administration of the Tuberculosis Orders is the police, but there are ways and means of the police being made use of if they can only be prevailed upon to do it. If they will go in their private clothes it will not be half so objectionable to the farmer. If a dairyman has police in uniform popping in and out of his place all along, it attracts the attention of his customers, and I find that if the farmers get a diseased animal they pack it off quietly to the knackers in preference to notifying and getting compensation. The consequence is that notification throughout the country is becoming practically a dead letter, although I dare say the veterinary practitioners do their duty. But the attendance of the police undoubtedly interferes with notification.

I will not say more except to add my personal thanks to Mr. Brittlebank for attending and giving us his interesting paper.

MR. WHITEHEAD: There is one question which Mr. Brittlebank brought forward to which I wish to refer—the question of meat inspection and post-graduate instruction. My own experience is that after coming out of College one is not competent to become an efficient meat inspector, and I am also of opinion that the great grievance of the butcher in the non-standardisation of meat inspection would be lessened if there was veterinary inspection of meat, and if all those veterinary surgeons inspecting meat had some time after their qualification had some post-graduate training, and in the course of that training had an opportunity of seeing what other men were doing—not what they were passing but what they were condemning. By taking this course one gets an opportunity of seeing the methods of men who have collaborated other men's experience. You would get the meat trade, which is undoubtedly an influential trade, to support the profession. Of course I am quite open to admit that many of us men in public work have not done anything great in the way of meat inspection. All I can say personally is that I cannot get the information—the butchers won't give it me.

Another matter is this question of the decentralisation of veterinary administration, and the appointment of veterinary officers for large areas. If every veterinary surgeon in his own area was *ipso facto* a public health official and an inspector of meat (I do not say the veterinary officer would go round looking around for meat), but if the sanitary inspectors were not allowed to do anything but only to report to the veterinary surgeons I think we would then make one great step towards doing away with a real grievance. At the present moment this is a very poignant question. One has only to go about the district and hear the butchers speak.

Then there is the question of the veterinary inspectors relation to public health work. Mr. Brittlebank I know is doing very useful work as regards buildings, but many local authorities will not go on with it until we get a new Public Health Act in which the veterinary officer is given a definite standing.

Mr. HOWE: I must say that I have been very much interested in hearing the address by Mr. Brittlebank. He is a well known authority, and I am sure any views he ventilates we always look upon as requiring our most serious attention.

The last speaker (Mr. Whitehead) incidentally referred to the sanitation of buildings. We shall never get any alteration whilst the legislation has to be dealt with by rural district councils, because the members are in some way interested, and when they are called upon to use drastic measures which involve heavy expenditure they do not press the matter.

I am very much interested in the subject of tuberculosis because I have had several cases to deal with since the Order came into force. We have been very badly handled in my county, although I do think that if there is anyone who tries to do their duty it is the members of our profession. They are not only worthy of their hire, but are, I am sure, as a profession, very helpful to the community.

Mr. POLLARD: The only thing I can say with regard to the Tuberculosis Order is that our experience is not quite the same as others with regard to the bugbear of the policeman. Our procedure is for the police to take the report and pass it on to the veterinary inspector. The chief trouble is with regard to compensation. I think they may as well away with it to the knacker and do away with the searching for other animals affected. Of course it does sometimes happen that there may be another case stowed away in some corner.

Of course one can see the importance of the ventilation of cowsheds. I agree with Mr. Brittlebank's remarks. The cleanliness of cattle is more a question with us.

Mr. E. G. JOHNSON: I should like to express what are my own feelings, that it is very gratifying to have an opportunity like this to call in the midst of our labours and hear such an able address as one has had the privilege of hearing this evening. In view of the fact that the general practitioner had some little prejudice against the official veterinary surgeon, the paper this afternoon proves that the veterinary practitioner is greatly indebted to the veterinary officer. We hear a great deal about the progress of the profession, and I take it that as members of the profession we are very anxious to take part in that progress. We live in times when motor, electric, and compressed air haulage are taking away a very great deal of our living, and for some of us who have seen the halcyon days of the profession and begin to view things with a rather pessimistic outlook, it is gratifying to know, through our friend Mr. Brittlebank, that there is a better prospect before the veterinary surgeons. He emphasised once or twice the young members of the profession, and it is gratifying to know that those who are young have some reasons to look forward hopefully; and even for those who are going gently down in the evening of our days there is something to soften the dying moments. I should like to emphasise that whilst it is stimulating to the young ones it makes some of us who are nearer 85 than 25 see that it is advisable for the profession to take advantage of the evolutions of the time.

I am very much gratified, not only from personal interest but from that happy spirit of *camaraderie* in our profession, that there are some matters in which we may co-operate to guide and direct these revolutionary changes so that they may be of advantage to our profession. I may say that experience has shown that Mr. Brittlebank has touched upon the main lines on which we ought to go. One is glad to know that one has the opportunity of meeting men who have the matter of the status of our profession at heart. We find wherever we go a noticeable desire to improve the status of our profession. In his paper Mr. Brittlebank has said we shall never advance much by jealousy, and

as a small body we shall not advance much by frontal attacks, but it is essential that every opportunity that is afforded for us to guide and direct legislation and administration which may happen for the good of our profession shall be seized. It does no doubt afford all of us pleasure to meet like this, and it would be better for us to meet more than we do, for the purpose of watching where our interests are concerned, and doing all we can with the co-operation of whole-time officials and practitioners to forward the progress of our profession.

This afternoon I have had the pleasure of hearing two gentlemen speak who are inspectors for two counties. I am an inspector for two counties, and in the two counties you have absolutely opposed conditions—you have a parsimonious and penurious group on the one side, and on the other, one gets quite fair treatment. In one county the matter is left almost entirely in the hands of the veterinary surgeon. I see another has had the same experience. We ought to stick at the former county through our Association, and get reasonable fees allowed.

I endorse what the President said—the chairman of a local authority often looks upon the veterinary officer simply as a man who takes his money out of the rates. We have always to remember this, Mr. Chairman, that whenever we are out to do something for the profession, whether we are seeking to ally ourselves with the Association, or whether we are seeking to ally ourselves with the servants of the city or of the county, we have strongly to avoid the question of self-interest. I have had occasion to speak at Farmers' Union meetings, and I have always been looked upon with a certain amount of suspicion. They should be made to feel that when you have a brief for bringing something before them it is for the public good.

Mr. LLOYD: I do not think I should be doing my duty unless I propose a very hearty vote of thanks to Mr. Brittlebank for coming here to address us to-day. It may have been unintentional on his part, but he seems to have been hitting me very hard. Anyhow the cap seemed to fit. He spoke about the pessimist and the frontal attacks. I am bound to acknowledge that I have been beaten, and in consequence I have become a pessimist. He has given us various reasons why we should not make frontal attacks, and why we, as a small profession, cannot hope to get any benefit from them. He has on the other hand given us one or two ways in which he thought we might possibly get some benefit. One of the ways was in reference to approaching agricultural bodies. That has been mentioned by one or two speakers, but I think has been taken up in a way that Mr. Brittlebank did not intend—he did not mean local, but national agricultural bodies—bodies like the Central Chamber of Agriculture, Animals Tuberculosis Committee, the Royal Agricultural Society of England, Highland and Agricultural Society of Scotland, and the Royal Dublin Society. They are bodies not influenced by the rates. They may not be bodies that are in very great sympathy with the veterinary profession, but they are in sympathy with us to some extent, and I think if we approached them we should get their support. I know that as regards the Central Chamber of Agriculture, Prof. Penberthy is doing his level best for the veterinary profession, and although he is not at present a practising veterinary surgeon, I have no doubt that his professional experience is standing him in good stead in his remarks to these bodies. What Mr. Brittlebank has not told us is how we are to approach these bodies, and I put it to members to-day to get up and suggest how we are to approach them. I have one or two things in my mind. I, for one, have been a member of the Council for four years, and during that time the Council have done nothing to enlist the sympathy of the agricultural bodies. Then

again there is the National Veterinary Association. Is this Society going to do anything to raise the status of the veterinary officer. Mr. Brittlebank, as you are probably aware, is a candidate for election to the Council of the Royal College of Veterinary Surgeons. I put it forward to Mr. Brittlebank that if he can get the Royal College of Veterinary Surgeons or the Council of the National Veterinary Association to move in this matter he will be a success.

Whilst speaking of the medical officer of health I am not going to run him down, but I will say this—that backed up by the Local Government Board, and backed up as he is by the Association of Medical Officers of Health, we, as a veterinary profession and veterinary officials, have no chance of improving our status in that direction. In 1901 I know that the Association of Medical Officers of Health passed a resolution that on no condition would they advise their Corporation to appoint whole-time veterinary surgeons excepting as subordinate officers to themselves. I do not know of any appointments since that time where that resolution has not been adhered to. We know that there was last week a big fight in Edinburgh with regard to the establishment of a Veterinary Department. Three members of the Health and three members of the Markets Committees were appointed to go into the question. This sub-committee was equally divided—three members voting for the establishment of a separate veterinary department, whilst the other three were in favour of it remaining under the Medical Officer of Health. The matter went before the Council, and it was decided to improve the conditions of the veterinary inspectors, but to leave them subordinate officials in the Medical Officers Department. If veterinary officers on retirement can only reach such a paltry salary as say £200 a year after many years service there is no wonder why eminent veterinary surgeons are not bringing up their sons in the profession.

Tuberculosis Order and meat inspection : Usually in regard to meat inspection a veterinary surgeon has to be appointed an Inspector of Nuisances before he has any power as meat inspector under the Public Health Acts. Under the "Sheffield Corporation Act, 1912," the veterinary inspector has the same powers as the medical officer or inspector of nuisances. The same thing applies in Swansea under one of their local Acts. In Sheffield also the administration of the Tuberculosis Order is entirely in the hands of the Veterinary Department—the police having nothing to do with it.

Some one mentioned a point about the diagnosis of anthrax. Now that is a point that is coming to the front very quickly. The county of Aberdeen is the most prolific county as regards anthrax. Not more than two-thirds of the "smears" that are sent up to the Board are confirmed, but in the meantime the farmers have had the carcasses of the affected animals destroyed and the premises disinfected in compliance with the Anthrax Order. They have had to pay insurance against anthrax, but because the Board do not confirm the local inspectors' diagnosis the insurance companies refuse to pay. I know the County Council are taking up this question, and are approaching the Board of Agriculture with reference to some change being made.

I have very great pleasure in proposing that Mr. Brittlebank be given a hearty vote of thanks for his presence here to-day.

Mr. Anson : I am delighted to second the proposition. I know Mr. Brittlebank extremely well and I am sure there is no member of the profession who is more able to give an opinion on the subjects which he has touched upon. I am sure we are all indebted to him for the splendid paper he has given us. Perhaps he has not touched the heart of all the members here, but his remarks may concern the members who are publicly

employed. He has dealt with the matter in a very searching manner, and I have very great pleasure in seconding the proposition.

The vote of thanks was carried with acclamation.

Mr. BRITTLEBANK : I need not say very much in reply, only to thank you for the kind way in which you listened to the few remarks I had to make, but I can say that I greatly appreciate your vote of thanks.

I know perfectly well that my subject is one which it is extremely difficult to treat to make it interesting to those who are not concerned in the spheres of work which we have to live in. I know that much that one has to say is regarded as rapid outpourings of an optimist, but in any of those questions of professional progress such as I think our profession is going through, I think there is distinct room for optimism. My way of looking at life is largely this—that if you go into the highways and byways crying stinking fish about your profession the public will accept you at your own assessment. If you go into the street and tell a man you are a fool he won't contradict you; but if you are able to convince people that you have some useful sphere on this globe, their influence to assist you to the new sphere of public service will not be withheld.

The discussion which has followed my remarks has been too kind. I expect really when a discussion of this sort takes place that one should put off the gloves and let us have a little bit of straight hitting. Mr. Lloyd, if I may be pardoned for referring first of all to him, referred to this question of hitting direct. When I spoke as I did I had no particular person in view. Mr. Lloyd and I have been very intimate friends for many years now. His views and my views are not the same, but Mr. Lloyd is Britisher enough to appreciate the fact that I would not come here to hit at him without saying that I was hitting at him. As a matter of fact the view that I take of the position is a sort of general survey of what we have achieved in the few years we have been in the public service, and we have achieved mighty little. Mr. Lloyd has let you into a secret which was known to a lot of us about the medical officer and his Association. Knowing this feeling very well, and knowing the unassailable position in which medical officers are placed, it behoves us to look around and see if there is not another method. The President wisely remarked that he did not think we could get the farmers to help us. When I threw out the suggestion I threw it out meaning the Council of the Royal Agricultural Association. I would not have anything to do with a local agricultural association. We know perfectly well that their view is limited to their own interests. We must go to someone who will look at it from the point of view of public policy as to whether it will benefit agriculture, and if it is so, and we can get their help, it may be of great assistance to us.

Mr. Lloyd referred to the Royal College of Veterinary Surgeons—at present I am only a candidate and am not prepared to say what they will do. I do think the Royal College and the National Veterinary Association should do something. Our National Association is newly constituted, and has really not yet had a proper opportunity of showing what it will be able to do. Unfortunately, we have lost our dear old friend Hunting, and there have been a good many things in the way of allowing the National Association to take steps in these matters. I regard the National Association as a sort of Trades Union. The term is perhaps objectionable, but its power and utility if properly carried out would be very great. The British Medical Association, which has been the model for our Association, has achieved an enormous amount of good for the medical profession, and if the National Association are statesmen enough to approach this problem in the same way, I feel they will be very largely able to carry out this object in the same way as is done for the medical profession. But I

do not think that will be done without the aid of the veterinary practitioner. In my humble opinion the interests of the profession are one, and I think the objects of the whole-time officer and the practitioner are one. If one progresses the other will progress, and it therefore behoves us to hang together and push the interests of the profession, not from a selfish point of view, but on the grounds of public policy if we are to accomplish anything which will be better for our profession.

Mr. Pollard referred to having no difficulty with the Police. One quite recognises that the policemen who are in cities and towns are not difficult to deal with, it is the County Police in country areas that I referred to more particularly.

Much of what transpired requires no reply. Mr. Pollard referred to the question of keeping cows clean. That simply requires a Bye-law under the Dairies, Cowsheds and Milkshops Order. In the City of Manchester we have a Bye-law, and any man who does not keep his cows clean may be prosecuted and fined.

Mr. Whitehead referred to the question of housing of stock. This is a national question, and I suggest that the whole of it should be under the control of the veterinary officer. In the city which I serve, no building for the housing of animals is allowed to be put up without my approval. The whole of the conditions are laid down by me, and the plans are all submitted to me before they are submitted to the Improvement Committee. The same applies to the reconstruction of old buildings. I think we shall be able to ultimately get complete control of the conditions under which animals live. The present conditions are grossly unfair. The

owners of property are frequently imposed upon. Going about the country districts as I do, seeing the patch-work jobs that are done to the instructions of medical officers of health and sanitary inspectors, it makes one sick at heart to realise the calls that have been made upon the owners of property, and which have effected nothing.

Gentlemen, I once more thank you very heartily for the very great kindness which you have shown me.

SPECIMENS.

Mr. S. E. SAMPSON exhibited a specimen of fracture of the os calcis, and also exhibited some crude splints which the farmer had applied to the animal under the belief that the fetlock was fractured, in order to keep it in its place.

The PRESIDENT exhibited the testicle of a pony in connection with which there had been a large growth for some years. Previous to the animal's death he had been under the impression that the growth was a diseased testicle, but upon post-mortem examination the testicle was found to be in a healthy condition with the tumour in apposition. It had not affected the animal's health in any way.

Also an improved needle for inoculation with "black-legine." He said that he found the needles usually supplied by instrument makers were too frail, often snapping off and in other ways being unreliable.

Also a large urinal calculus, which had been passed by a horse in the practice of a friend.

Mr. HUDSON (Retford) exhibited a specimen of cod fish in which were embedded a number of thread worms.

A vote of thanks to the President terminated the meeting.

Animal Diseases—Demand for Research.

At a meeting of the Berks and Oxon Chamber of Agriculture on Saturday last it was proposed—"That further research in swine fever should be undertaken at one or more University centres as well as at the Government Laboratory at Alpertón."

Some difference of opinion was shown on the question whether official research—as opposed to research at a University—is or is not necessarily biased, but all those taking part in the discussion acknowledged the advantage of free and full inquiry.

A letter was read from Sir Clifford Allbutt, Professor of Physic at the University of Cambridge, in the course of which he wrote—"Let me ask you whether the time has not come to abandon the method of slaughter, or at any rate to regard it with profound dissatisfaction and as a mere wasting of time. What, then, ought we to do to obtain knowledge of swine fever? My answer is, refer it to University research. Animal medicine will never come to its own, nor indeed will man medicine either, until the subject of disease is recognised and grappled with as a whole. Medical observation of plague would have been to-day where it was 20 years ago if the observer of man had neglected the rat and the flea, and malaria and yellow fever would still be raging unchecked if the flimsiest of gnats had escaped the ubiquitous vision of the comparative pathologist."

Sir John McFadyean brought forward statistical evidence to show that since the control of swine fever had been in the hands of the Board of Agriculture—a matter of 20 years—a steady decline in the number of outbreaks had taken place. From 6,305 outbreaks in 1894 the number had fallen to 2,573 last year. The net result of the 20 years' administration was a 50 per cent. reduction in prevalence. The present position, however, was somewhat disappointing, because complete extermination had not been accomplished. He believed that a thorough system of isolation and slaughtering of infected pigs, and pigs in contact with them, would end this disease as it had ended cattle plague. The conditions in this country were superior to those in foreign countries.

The assertion that the Board of Agriculture, in virtue of its powers, centralised all control and reserved to itself all experimental research in connection with contagious animal disease was erroneous. The suggestion that the public could not get independent advice was without foundation. Nor was it true that the Board of Agriculture in any way biased the minds of its workers. It was an accolade to them to assert that the veterinary colleges in this country were incapable of conducting research and that no useful research had been carried out at home.

Dr. Greenwood said that it was necessary to compare things which were alike. Before 1893 the diagnosis of the disease was faulty, and there was reason to believe that many outbreaks were called swine fever which in reality were nothing of the kind. Moreover, measurement by "outbreak" was inaccurate. One outbreak of diphtheria in a city might be a much more serious matter than 10 in small villages. His own work showed that the disease, swine fever, had increased over a 12-year period in the proportion of 15 to 22.

Dr. Nuttall associated himself with the plea for university research. He believed that research carried on by official bodies was apt to be biased. He knew of cases where results had been obtained contrary to those desired by the bodies paying for the research. These results were pigeon-holed and hidden away. One piece of work performed in this country had been thus pigeon-holed during two years, and he could tell of cases occurring in Germany, France, Italy, the United States, Africa, India, and Australia. It was a disgrace

that veterinary science had not more recognition. The time had come to link up human and animal medicine, and the linking would be a great advantage to both, and would help to clear up many obscure disease problems. At Cambridge they had made a start, and they were determined to go on.—*The Times*.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, May 5.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Sqdn. Sergt.-Major A. Robb, jr., from the Lanarkshire (Queen's Own Royal Glasgow and Lower Ward of Lanarkshire) Yeomanry, to be Lieut. Dated May 6.

Personal.

GOLLEDGE.—On April 13th, at Ashford, Kent, the wife of Hedley C. D. Golledge, M.R.C.V.S., of a son.

DIXON—SCARLETT.—At Holy Trinity Church, Margate, on Wednesday, 29th ult., a wedding took place between Miss Constance Emily Dixon, daughter of Mr. Edward Lyne Dixon, M.R.C.V.S., of Granville House, The Grosvenor, Margate, and Mr. John Walter Scarlett, son of Mr. and Mrs. John Walter Scarlett, Beechcroft, Newington, Ramsgate. Both Bride and Bridegroom come of well-known Thanet families, and the esteem in which they are held was shown by the large attendance at the church.

The service was fully choral, the hymns sung being "The Voice that breathed o'er Eden," and "O! Perfect Love." Dr. Bellerby presided at the organ.

The bridesmaids were Miss D. Scarlett, sister of the bridegroom, Miss Bobby, and Miss Bellerby, and Mr. Ernest Dixon, M.R.C.V.S., acted as best man.

An interesting feature was the attendance of twenty ladies of the Margate Ladies Hockey Club (of which the bride was captain) who formed an archway with their hockey sticks decorated with white satin, under which the couple passed as they left the church.

The honeymoon is to be spent at Torquay. The presents, which were very handsome, numbered over one hundred.

After the ceremony a reception was held at the Naylor Rock Hotel, amongst the guests being the Mayor and Mayoress of Margate (Alderman and Mrs. W. B. Reeve), the Mayor and Mayoress of Ramsgate (Councillor and Mrs. G. G. Cook), Alderman D. T. and Mrs. Evans, Dr. and Mrs. C. F. Lyne Dixon, Mr. and Mrs. Walter Hills, and others, the guests numbering 175 in all.—*East Kent Times*.

No. 1349.

MAY 16, 1914.

Vol. XXVI.

THE COUNCIL ELECTION.

This year's Council election is important in one respect—it will introduce new blood to the Council to the extent of nearly ten per cent.

There are eight vacancies; and only five of the retiring members—Messrs. Abson, Banham, Mason, Shipley, and Sumner—are seeking re-election. All these are almost certain to retain their seats. Four new candidates—Messrs. J. W. Brittlebank, of Manchester; J. C. Coleman, of Swindon; P. J. Howard, of Ennis; and T. C. Toope, of Dover—are competing for the three vacant seats. All are new at the polls, but all are well-known men and thus the election is a very open one.

No test question is before the electors—we must be guided simply by our estimate of the personal fitness of the candidates for the general work of the Council. We want men who are able and willing to give up the necessary time, and who possess, not necessarily brilliance or showy qualities, but sound common sense and practical business capacity to bring to the work. All the nine candidates have been sufficiently before the profession to enable us to form a judgment as to how far they possess these attributes. A few minutes devoted to considering the individual endowments of each in turn will be time well spent.

APPOINTMENTS ABROAD.

No less than ten foreign appointments for veterinary surgeons have just been advertised—two by the Queensland Government, and the others by the Crown Agents for the Colonies. Without special knowledge of the countries it is impossible to say what the salaries offered really represent in English money. Probably they are something like the salaries of most whole-time veterinary appointments in England—rather more than the earnings of the average practitioner, but nothing like those of a few very successful ones. The most serious objections to these foreign posts are the isolation and frequently excessive work they entail, and the fact that some at least tend to unfit their holders for other work.

Still, we think they are well worth the attention of young graduates of good constitution, but those whose thoughts are turning towards them should not delay too long. At present there is no lack of such openings for suitable men. But in a very few years the new Melbourne College will be turning out graduates whose training ranks equal with ours; and for Australasia and Malaysia at any rate, they will be formidable rivals for Government posts.

PECULIAR CALVING CASE.

On April 24th, about 11.30 a.m., I was called to a calving case. The messenger said there was something strange coming, and that the cow was very sick for the last two hours.

On arrival I found the intestine protruding from the vulva, and on passing in my hand I found a large cone-shaped body in the womb, the surface of which was quite slippery and without hair. This body resisted all attempts at manipulation and after prolonged search for a limb or head I recommended slaughter, which was accordingly carried out. The resulting examination revealed a monstrosity.

The abdominal organs were developed and hanging loose—not enclosed. The skin from the abdominal region was reflected back over the quarters and formed a sac which, on being slit open, presented an extraordinary condition. From this reflected portion of skin there were hanging three legs developed from the carpus only downward. The head and neck seemed to be developed from the sacrum, the head lying beside the tail, and attached to this portion of the trunk there was also one fully developed fore leg. The hind legs were normal in shape and position and the anus and vulva *in situ*. The thorax was absent.

The case may be of interest to embryologists.

A. F. O'DEA, M.R.C.V.S.

New Garden, Tuam.

EXPERIMENTAL RACHITIS IN YOUNG ANIMALS BORN OF PARENTS DEPRIVED OF THEIR THYROID.

Henri Claude and J. Rouillard record (*C. R. Biologie*) the following experiments. They removed the thyroid glands from a male and a female adult rabbit, weighing about three kilogrammes (=approximately 6.6 lbs) and coupled the pair a few days later. Gestation, the birth of eight young rabbits, and lactation, which lasted forty days, took place in normal conditions. Four of the young rabbits died about the third week, with distension of the abdomen. One survived, and developed normally. The other three died in a cachectic condition after ten to twelve weeks. Their weight was about 50 per cent. less than that of control rabbits brought up in the same conditions.

The post-mortem examination of the three cachectic rabbits and the microscopical examination of their bones revealed unmistakable skeletal lesions of rachitis. In the pathogeny of rachitis, therefore, a certain amount of influence should be

accorded to hereditary or acquired thyroïdal insufficiency.—(*Annales de Méd. Vét.*)

THE USE OF LABARRAQUE'S FLUID IN SURGERY.

Frederikse and Gallandat Huet drew attention (*Tydschrift voor Vecartsenrykunde*) to the good results which may be obtained from Labarraque's fluid. They state the following formula for the preparation—hypochlorite of calcium 33 parts, carbonate of sodium 67 parts, water 1000 parts. After mixing, the liquid is allowed to stand for 24 hours, and then that portion which is very clear is decanted. Labarraque's liquid has been known for a long time, but its use is now almost totally abandoned. The authors have tried it twice with very happy results.

Their first case was a mare suffering from an abscess in the frog. Some warm baths caused the abscess to open, and the resultant cavity soon became covered with granulations; but a persistent fistula remained. Antiseptics, and also plugging with corrosive sublimate, were tried without avail; and the fistula was becoming worse. The foot was then immersed for half-an-hour daily in a bath containing 2 per cent. of Labarraque's liquid. Rapid improvement followed, and recovery was complete after five weeks.

The second case was one of poll-evil, and presented a fistula which commenced about 1 1/5th inch from the median line, and was directed towards the cervical ligament. Two counter-openings were made; and for some days these were kept patent by drainage tubes and syringed with hydrogen peroxide solution. The case was becoming worse; and the authors altered the injections to a 2 per cent. solution of Labarraque's liquid. This was injected four times daily. The suppuration soon diminished, and it became possible to remove the drainage tubes. The treatment was completed by the injection, for a few days more of a mixture of tincture of iodine, tincture of myrrh, and tincture of arnica, in order to stimulate reparative granulation.—(*Annales de Méd. Vét.*)

CONTAGIOUS AGALACTIA OF SHEEP AND GOATS.

H. Carré has published (*Annales de l'Institut Pasteur*) an article upon this condition and the results of a very complete clinical and experimental study of it which he has made.

The malady is a contagious one, and is propagated by milk. It is due to a filtering virus, which is eliminated by the milk. The disease, when inoculated experimentally, presents the same characters as the natural disease. It is easy to diagnose, and presents both general and local symptoms.

The general symptoms consist of fever, general enfeeblement, loss of appetite, and, in the acute form, rapid death. In the chronic form, these general symptoms are very slight and may even pass unperceived.

The local symptoms involve the udder, the eye, the joints, and sometimes even the skin. The udder, after showing violent inflammation, becomes atrophied and develops indurated centres of variable size. One or both quarters may be affected.

The articular localisations attack the carpus and tarsus by preference, and then the femoro-tibial, humero-radial, coxo-femoral, and metacarpal articulations, rendering all movement painful and impossible. The eye presents a simple opacity of the cornea, or parenchymatous keratitis, internal ophthalmia, and sometimes purulent complications.

Abscesses, due to common pyogenic organisms, are found in various regions, such as the parotid mediastinum, and muscles.

The animals lose condition considerably, and die in a state of complete cachexia.

This disease is prevalent in the departments of the South-east of France, where it occasions severe losses.

The result of Carré's independent study of it is summarised as follows:—

(1) For a space of some months, until it is completely atrophied, the agalactic udder may secrete a liquid which is equally virulent during the whole course of the disease. (This conclusion of Carré's is contrary to the opinions of other workers).

(2) For the disease to be contagious, it appears indispensable that the patients should bear open lesions. Lachrymal discharges from an affected eye, even without ulceration, are virulent.

(3) The virus of the disease is perfectly absorbed by the digestive passages, and this method of infection seems to be much the most important one in its propagation.

(4) It is possible to create an abundant source of pure virus by inducing an experimental pleural exudate.

(5) The serum of hyper-immunised animals possesses very distinct preventive properties.

(6) Sero-vaccination which has been accomplished in the laboratory, appears bound to render great prophylactic services against the disease.—(*La Semaine Vét.*)

THE TREATMENT OF TUMOURS IN DOMESTIC ANIMALS BY THE RÖENTGEN RAYS.

Dornis has published (*Zeitschr. f. Veterinark.*) the results of attempts he has made in the treatment of malignant tumours in horses and dogs by the Röntgen rays. He first describes five favourable cases. The first was a horse, age not stated, affected with spindle-celled sarcoma. One tumour, the size of a potato, was present upon the right upper eyelid, and a second one under the lower eyelid. The tumours were removed and the wounds cauterised, but the wounds very quickly became covered with local recurrences in the shape of wart-like growths. The Röntgen rays were then applied every three days, for fifteen or twenty minutes at a time. At each application the proliferating masses assumed a bright red colour under the influence of the rays, and became copiously covered with a serum-like fluid. After twenty applications there was a vigorous growth of epithelium from the edges of the wound. The treatment was discontinued, and a year and a quarter later no recurrence had taken place.

The second case was a black dog, fifteen years old. A melano-sarcoma, the size of a hen's egg,

was surgically removed from the inguinal glands. New sarcomatous masses appeared in the wound cavity, and these, after nineteen applications of the Röntgen rays, were replaced by healthy granulation tissue. No recurrence took place.

The third case was a dog, age not stated, with a round-celled sarcoma, the size of a walnut, in the inguinal glands, and numerous small ones, ranging from millet-seed to pea size, in the skin of the lower part of the thorax and abdomen. Under the Röntgen rays the small tumours gradually decreased, without the formation of cicatricial tissue. The larger one lessened to the size of a hazel nut, and was then extirpated. No recurrence followed.

The fourth case was a dog, age not stated, from whose inguinal glands a round celled sarcoma had been removed a year before. This was followed by the appearance of another round-celled sarcoma under the skin in the fold of the knee, which attained the size of a walnut. It was then extirpated, but new tumour tissue appeared in the wound. After the Röntgen rays had been applied twenty-four times the surface of the wound was healthy, and no recurrence took place.

The fifth case was a dog, age not stated, with a superficially situated squamous epithelioma round the anus, which caused difficulty in defecation. After nineteen applications of the rays, the owner was satisfied with the result that had been attained. (What the result really was is not stated.—Transl.)

Dornis then proceeds to the cases which were unsatisfactory. He repeatedly failed to get good results in cases of sarcoma of the maxillary sinuses in horses. Four cases of mammary carcinoma in bitches were all failures. In one cancrroid growth of the nasal cavity in a dog the rays seemed to have a direct irritant effect. One fibro-sarcoma in a horse, and another in a dog, were also failures.

These results confirm the general experience that the Röntgen rays exercise a pronounced destructive effect upon tumours which are rich in cells, well provided with blood vessels, and inclined to recurrence (those, therefore, of a more embryonal character), and that more organised tumours, carcinomata (especially fibro-carcinomata), and many mixed sarcomata, are more resistant to the rays. A previous operation, such as was performed in most of the successful cases described above, greatly facilitates treatment by Röntgen rays.—*Berliner Tier. Woch.*

EQUINE PIROPLASMOSIS.

M. Carpano discusses this subject. (*Zentralbl. f. Bakt. Parasitenk., u. Infektionskr.*) Equine piroplasmosis can be caused by two distinct types of parasites. One called *Nuttalia equi*, is of fairly small dimensions and is characterised by a peculiar reproduction into four elements arranged cross-wise. The other is called *Babesia caballi*, is of large size, and propagates in the circulating blood by means of a true gemmation process. The two types are encountered in many regions of the Old World in particular, and *Nuttalia equi* is much more widely spread than *Babesia caballi*.

Both these types occur in Italy, but *Nuttalia equi* is found the most frequently, and has the greatest

area of distribution. In the colony of Erythræa, according to the author, only *Babesia caballi* has hitherto been observed. Many of the horses native to Erythræa possess a certain degree of immunity, which stands midway between natural and acquired immunity. Imported horses, on the other hand, are very susceptible.

Clinically and anatomically, the two diseases caused by these two parasites show no very pronounced distinctive characteristics. Some peculiarities, which are attributable to conditions of time and place, are possessed by both types. The natural infection apparently takes place through agency of *Rhipicephalus bursa* and *Boophilus annulatus*. The last-named is the transmitter of *Babesia caballi*.

The disease may be transmitted artificially by means of infected blood. Cases in which attempts at transmission have had negative results are attributable to immunity of the experimental animals. Horses which have once suffered from one of these piroplasmoses and have recovered remain immune against the same type of piroplasm for a varying period. On the other hand, horses immunised against *Nuttalia equi* can be infected by *Babesia caballi*, and vice versa.—*Berliner Tier. Woch.*

W. R. C.

NORTH WALES

VETERINARY MEDICAL SOCIETY.

[NATIONAL V.M.A. NORTHERN BRANCH].

CLINICAL POST-PHARYNGEAL SURGERY.*

By R. JONES, M.R.C.V.S.

In response to an appeal from our Secretary I propose giving a brief account of a few cases of diseased condition of the region of the throat which called for surgical treatment, so as to give immediate relief and to effect a cure.

Case I. A three-year-old bullock, which had been suffering from actinomycosis of the back of the tongue and throat early in the winter. The affected parts were painted with Tinct. iod., and Pot. iod. was given internally. I ceased to attend, and he was reported to have apparently recovered. In the spring he was turned out with the rest of the bunch, and in the course of some weeks the bailiff reported that the same bullock was exceedingly bad, constantly coughing and making a distressing noise during respiration, practically unable to graze, and that he would be taking him up from grass past my premises at a certain hour. When passing I examined his throat and could see a tumour at the back of the pharynx, hanging in front of the larynx; the symptoms were as described by the bailiff, and the bullock fallen off in condition.

I arranged to go the following morning to destroy him if unable to remove the tumour with a view of ultimate recovery.

In the struggle and exertion when being thrown he became exhausted before I completed the tying, and had I not hurriedly opened the trachea he would have suffocated. He immediately recovered when the breathing was relieved. A tracheotomy tube was inserted, and I placed a mouth gag and examined the throat; there was a mushroom-shaped tumour attached by a

* Read at the March meeting of the Society.

pedicle about 1½ inches to the posterior surface of the pharynx. I tried to tear through the pedicle with my fingers, but failed. Without much difficulty I got the écraseur chain round the pedicle close to the mucous surface and removed the growth. I did not see the case afterwards, but my daughter called daily to dress the tracheotomy wound, which was soiled by a little food escaping. Nothing further was done to the throat, and the animal was fed on mashes and a little grass for some days. He made a complete recovery and was sold with the rest.

Case II. I was asked to see an in-calf heifer which was making a noise in breathing, and proceeded to examine the throat. It proved an extremely difficult matter to make anything like a thorough examination of her, and I decided to let her calve before doing anything further, as she was able to graze fairly well.

I was phoned to, and told that she had calved some days, and the condition of the throat was such that the breathing was very distressing and the heifer was unable to take any nourishment. From what I could see and feel in the throat when making my first examination I suspected an abscess on the superior surface of the pharynx. I had her taken out of the building to a field close by, never suspecting that the difficulty in breathing was such that there would be any danger of suffocation in the struggle of throwing. It was proved that I was wrong in my conjecture, for I had to open the windpipe hurried in this case also, and insert a tube.

When the gag was placed in her mouth I made a manual examination of the throat and found the superior surface of the pharynx much swollen, thereby interfering with the breathing and deglutition. With some force I pressed my finger through and made a forward tear in the membrane. This was followed by a gush of pus, and I immediately placed my hand on the tube in order to assist her in coughing any matter that might have been escaping down the trachea. No further treatment was applied to the throat, but the tracheotomy wound was dressed daily.

The moral from these two cases is—never to operate on the throat when there is difficulty in breathing without previously performing tracheotomy.

Case III. This case was on the same farm as No. II. A barren cow which had what appeared to be a tumour, deep in the neck in the jugular furrow a few inches from the larynx, between the trachea and the cervical vertebræ. Such was the pressure exerted by the swelling that the trachea was pressed downwards, giving to the lower aspect of the neck a distinct curve. When I first saw the cow she was able to take nourishment fairly well, and I gave the owner a bottle of liniment to rub on with a "wait and see" idea.

In the course of a few days I had a message saying the cow was unable to swallow anything, but that the breathing was not interfered with. I pointed out to the owner that there was a certain amount of danger in the operation, and he said "It is a case of operating or dying."

The cow was thrown on her right side, and whilst I was washing the seat of operation the chloroform mask was put on. When she was got under the anæsthetic I made an incision about five inches long, and dissected carefully down on what proved to be an abscess. I pressed the jugular vein upwards, and the long muscle of the neck (sterno-maxillaris) downwards. When I had dissected on to the swelling I ordered one of the men to put his hand on the opposite side of the neck and press the enlargement towards me. I inserted a trocar and canula, and when the former was withdrawn thick pus oozed out. I used a director to guide the scalpel and made a good opening in the abscess and washed the cavity out. I separated the muscle and tissues from the trachea, and made an incision through

the skin on the lower aspect of the neck, opposite the operating wound, so as to ensure good drainage.

The abscess cavity and the drainage wound were syringed every day. The communication between the two wounds was kept patent until the abscess cavity had completely healed.

The cow eventually recovered and gave no further trouble. The amount of blood lost during the operation was quite insignificant.

ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION.

NATIONAL V.M.A.—SOUTHERN BRANCH.

An ordinary general meeting was held at the Crown Hotel, Faringdon, on Friday, April 24. The chair was taken by the President, Mr. J. C. Coleman, Swindon; and there were also present: Messrs. G. P. Male, Reading, Hon. Sec. and Treas.; J. H. Parker, Faringdon; J. Willet, London; S. H. Slocock, Hounslow; W. T. D. Broad, Marlborough; and J. Baxter, Lechlade, members; and Messrs. Hugh A. McCormack, Secretary of the Central Association, London; W. H. Brown, *Veterinary Record*, London; E. E. Seldon and E. C. Bowes, Tetbury; T. C. Toope, Dover; and J. H. Parker, jr., Faringdon.

Apologies for inability to attend were received from Prof. McCall, Prof. Brayley Reynolds, Capt. O'Rorke, and Messrs. Hurndall, Jagger, Shipley, P. J. Simpson, Stanley, H. G. Lepper, T. W. Lepper, Cundell, Villar, Hazelton, McKerlie, Tennant, King, and Hanks.

THE LATE MR. WM. HUNTING.

The HON. SEC. read a letter from Mr. Carter, President of the Royal College, asking this Association to express assent to the petition which it is proposed to present to the Treasury in favour of a pension to the children of the late Mr. William Hunting, and enclosing a form of the petition. Mr. Male added that the petitions were now being called in.

On the motion of Mr. Slocock, seconded by Mr. Willett, the President was requested and empowered to sign the petition on behalf of the members.

NOMINATIONS TO COUNCIL.

The HON. SEC. submitted a letter from the Joint Veterinary Association (Ireland) asking him to bring under the notice of the members of this Association the fact that Mr. P. J. Howard, of Ennis, had been nominated; and asking the members of this Association to vote for Mr. Howard if they could see their way to support him.

Most of them, Mr. Male said, knew that Mr. Coleman was desirous of going on the Council. They might make a compact, perhaps, with other Associations to support each other's candidates. (Hear, hear.)

Mr. TOOPE said that, with Mr. Coleman, he was also a candidate for the Council on behalf of the South Eastern Counties, and he had asked for the support of the Southern Counties and the Eastern Counties, and he now asked for that of the Royal Counties. Yorkshire and Lancashire had twelve men, and the Central thirteen on the Council, and he thought it time there was some combination in the South and East.

Mr. SLOCOCK observed that the Central had always, quite rightly, kept clear of veterinary politics.

Mr. WILLETT proposed that an affirmative reply be sent to the letter, provided that the joint Irish Associations would use their endeavour to support the candidates of this Association.

Mr. MALE seconded the motion, and it was carried unanimously.

New Members. Mr. W. G. GREEN, M.R.C.V.S., of Boscombe Park, Bournemouth, nominated at the last meeting by the President, seconded by Mr. Broad, was unanimously elected a member of this Association.

Mr. SELDON, of Tetbury, was proposed by the President, and seconded by Mr. Male, for election at the next meeting.

ROYAL SANITARY INSTITUTE CONGRESS.

Mr. WILLETT moved, and Mr. Slocock seconded, and it was unanimously agreed, that the President be asked to represent the Association at this Congress, to be held at Blackpool.

Next Meeting. After some discussion it was resolved that the next meeting of the Association be held in London on the 7th August, during the meetings of the International Congress.

TITLE OF THE ASSOCIATION.

Mr. SLOCOCK, in accordance with notice given at the last meeting, proposed that the title of the Association be altered to "The Royal Counties Veterinary Association" by the omission of the word "Medical."

Mr. MALE seconded.

Mr. TOOPE and Mr. Broad having spoken, a vote was taken, when only five voted, two members supporting Mr. Slocock and three voting against. The resolution was accordingly declared lost.

DEMONSTRATION ON CASTING.

The party then adjourned to the stable yard of the Hotel where Mr. J. H. Parker, who some time ago contributed an illustrated article to *The Record* on the subject, gave, with the assistance of his son, a very interesting and instructive demonstration of hobbling and casting for castration by the method he favours. The demonstration was very successfully carried out on a fine Shire colt.

PROPOSED VETERINARY INSPECTORS' BRANCH.

Mr. TOOPE spoke upon the proposed formation of a Veterinary Inspectors' Branch of the R.C.M.A. He reminded members that he attended the last meeting of the Association for the purpose of interesting them in a suggestion which he was making throughout the South and East of England—the formation of a Veterinary Inspectors' section by each Society. Briefly the object was union, and not separation, which union, he believed, would be promoted by Inspectors' meetings being held in connection with Societies' meetings. That would bring about a better feeling, there would be less jealousy and less fear of what he might almost term opposition to the veterinary inspectors. That union, which appeared to be absolutely necessary, would be best in connection with local societies, and affiliated to the National Veterinary Medical Association. He was glad to know there was now practical union, but what he wanted the Royal Counties to do was to officially recognise the movement, and form a distinct section of the society, and he thought good would come of that. He proposed that from each of the counties from which they drew their members the veterinary inspectors should be represented by two or three on the Council of the Society, and that matters which concerned them alone should be discussed at the meeting of the section an hour or so previous to the general meeting of the Society. By doing that they would add to their numbers and retain them, because any Society doing that possessed the interest of the veterinary inspector who, if not already a member, would very shortly become one.

Mr. MALE asked how he proposed that the Inspectors' Section should be financed?

Mr. TOOPE did not think that anything of that kind was needed. The Secretary of the Society, who was a

veterinary inspector as well, would do the necessary secretarial work for nothing, and if a special meeting was necessary for inspectors only—which had not yet occurred—there might be a special whip round among them. The expense of the literature was met by the National.

The PRESIDENT: Do you not think that it is rather clashing with the National veterinary inspectors?

Mr. TOOPE did not think so at all. The idea seemed pretty general that the National veterinary inspectors were practically *non est*. Nothing appeared to have been done by them.

The HON. SEC. read a letter from Mr. P. J. Simpson on the point, in which the gentleman wrote—"Should the Royal Counties Society have a branch for inspectors, or should the inspectors resident in the Royal Counties area form a sub-branch of the National Association of Veterinary Inspectors? It seems to me that it is a pity to have too many sub-divisions, as surely the inspectors of each county can discuss their own affairs, and if unsatisfactory refer the matter to the National Society of Veterinary Inspectors, who could take the matter up on their behalf in an even stronger way than a branch of the Royal Counties Veterinary Association. The formation of these branches in existing veterinary societies tends to weaken rather than to strengthen the National Inspectors' Society, and I do think we ought to try to hold that together. I think you will agree with me that what was done in Berkshire in a quiet way could be done in other counties, and if that is refused, refer the matter to the National Society of Inspectors."

The PRESIDENT said he held with Mr. Simpson that the inspectors in the different counties should "put their heads together" and then put their grievances before the local authorities. He was afraid that as a section of the Royal Counties they would be powerless.

Mr. TOOPE said that hit the point he wanted to hit. Why could not inspectors, having considered improvements in various matters, delegate two of their members as representative of that Society, and in that way pass the thing on to the National Society?

The HON. SEC. said he had sent out about 50 notices to veterinary inspectors, and also a special request to members to attend that meeting. The poor attendance that day was rather disappointing, and did not seem to show much enthusiasm for an Inspectors' branch.

Mr. WILLETT moved that the matter be postponed until the general meeting at Reading, when there would be a more representative gathering.

Mr. MALE, who seconded, thought the general body of members should express an opinion before action was taken.

Mr. TOOPE said he quite agreed that the meeting should be representative. The motion was agreed to.

THE WORKING OF THE TUBERCULOSIS ORDER.

Mr. SLOCOCK opened a discussion on this subject. It would suffice his purpose, he said, if he simply set the ball rolling, as several of those present had had considerable experience in the working of the Order.

His own impression was that the Order—which he regarded as a preliminary "feeler"—was from that point of view very discreet, very sufficient, and very workable, although points in it were very puzzling. The fact of its being on quite new lines had made it difficult for them to fall in with it. They had the sanction of the Treasury that out of the moneys voted by Parliament half the compensation paid by the local authorities should be refunded for five years. The contention, he believed, was that the call on the local authorities would be very heavy for those preliminary

years, and either that it would not be so heavy after the end of the five years, so that they could stand the whole expense themselves, or that another Order would be substituted within that time—and possibly a more comprehensive Order. The present Order was dealing with tuberculosis in a very modified form—tuberculosis of the udder, tuberculous milk, and tuberculosis with emaciation. All cases of suspicious udders had to be inspected by the veterinary inspector, and all cases of emaciation in which tuberculosis was suspected. That gave the veterinary inspector the right of entry and to examine the rest of the animals on the premises, so that he could go through the whole herd. He had not to find out which of the animals were tuberculous, but which had tuberculosis within the meaning of the Order—which, of course, was very limited. The point was that it gave the veterinary inspector authority to go on those premises, and in that way it did great good from the inspector's point of view. Any milking cow which was a "waster," with a tuberculous udder, could be weeded out. It had become a trade with certain men to buy up those old cows, and they had been induced to traffic in them by owners who were anxious to get rid of them. It seemed essential nowadays, with that chance of inspection of herds, that the owner should not have on his premises any suspicious animals. He invited the dealer to buy them, and the dealer bought them at his own price and carted them away to different centres, one of those centres being the London Market. There an extraordinary number of emaciated animals had been killed, and that accounted for the small numbers appearing on the summaries given by the local authorities of animals condemned. They were inspected in the London Market, where emaciated and tuberculous animals were destroyed. The dealer gave, say, 30s. or £2, took them to London, and stood his chance, and there was always the "salvage." Supposing eight out of twenty were condemned, the dealer stood to win. He (Mr. Slocock) thought the thing had been winked at, and that he could substantiate the statement. [The President: I endorse that.]

In Article 10 of the Order, which dealt with the detention or isolation of suspected animals, it was provided that an animal might at any time be slaughtered by the owner or person in charge.

A point which he took as flattering to the veterinary surgeon was that the intimation might be given direct to the veterinary inspector instead of to the police, but that, of course, was controlled by the way in which the Order was administered in the different counties. There was throughout the Order a lenient idea on the part of the Board of Agriculture that no excessive notoriety should be given. The trade of a man known to have been supplying tuberculous milk would be gone, and there would be no attempt on his part to assist the Board in a quiet way in the eradication of affected animals, whereas it was hoped that in a lenient way the matter might be got quietly settled within the meaning of the Order; and the inspector might persuade the owner to have all his animals tested and to segregate all which were reactors, and so, if possible, eliminate the affected animals from his herd. Those animals in which the disease was not far advanced would feed out as very good meat—of a sort. (Laughter.)

The valuation for compensation was made on the easiest terms possible. Before an animal was slaughtered they had to get provisional consent between the owner and the local authority as to valuation, and no arbitrary method was suggested. The important point from the veterinary surgeon's point of view was that of the definitions. In Article 8, par. 4, the Board had laid down a very good definition of advanced tuberculosis; but a difficulty had arisen there. They could get tuberculosis in both lungs—three nodules in one and two in the other. He had not seen his way clear

to declare that to be advanced tuberculosis. Where tuberculous lesions were present on the *pleura* and the *peritoneum* they might take it to be an advanced case.

Under Art. 8, where a carcass was emaciated and tuberculous lesions were present, they had many difficulties. He thought all the inspectors in Middlesex had fallen into the trap—he knew that he had. (Hear, hear). He had had cases of emaciation in which the animal had definitely reacted to tuberculin, and on a post-mortem he had found lesions, but they had been so very limited that he could not see his way to certify definite tuberculosis. Now he was more agreeable to fall in with the view of the Board—that it was a case of advanced tuberculosis "within the meaning of the Order," because he took it such an animal was unfit for human food, and absolutely valueless on the market for any other purpose. (Hear, hear).

As to the precautions to be adopted with respect to milk, the Order allowed milk to be used provided it was boiled. In his opinion that permission should never be given. (Hear, hear). Tuberculous milk was a source of danger; and if it was so thoroughly boiled as to render it innocuous it could not be an advantage in any way. He thought such milk should be destroyed.

The case of suspected animals in markets and fairs was in his opinion very wisely and reasonably provided for, although he acknowledged that there would be difficulty when they came to the London market.

A rather unfortunate point as to veterinary inspectors was the amount of writing entailed. (Hear, hear). The reports required were something enormous—in fact one never knew when he had finished reporting on an individual case. The only compensating feature he could see was that they got the compensation which a solicitor got in a "good" case where there was a squabble—increased remuneration. (Laughter). If the fees were proportionate to the work they would get repaid, but on that point it seemed to him that the working of the Order in the case of an animal worth, perhaps, 30s., raised the question of what the veterinary inspector was to take out of it to be repaid for the work he did. The local authority had to consider that point presently; but he was afraid pressure would be brought on the Board of Agriculture, in the formation of any new Order, and that it might not improve matters for them. His advice, if he were asked, would be to work the Order as long as it lasted, for he did not think they would ever get a better. They would get a more comprehensive one, but he doubted if so much work would be thrown in their own hands. The question of compensation to the owner was very complicated, and it wanted a man who was pretty well an accountant to work it out; but thank goodness that was not deputed to the veterinary inspector.

He had always made it a point, in justice to himself, to the owner, and to the veterinary surgeon employed for the post-mortem, to invite the owner to have his own veterinary surgeon present at the post-mortem.

Mr. BROAD said it seemed to him silly to have two valuations. Only one valuation was made in the market in the old days. Personally he did not know, under the present system, how to value an affected cow. The owner, he thought, should be allowed to send some animals to the knackers, and let the post-mortem be made at the owner's own expense.

Mr. SELDON said the crux of the whole thing, as far as his division was concerned, lay in the valuation. He thought one valuation should be made, and that of the value of the animal as it stood on the day. Where one valuation might be 30/-, and the other £16, the owner got the idea that he ought to receive the latter sum. Unfortunately the tuberculin test was not infallible. It put a great onus on an inspector who condemned an

animal that reacted if on a post-mortem they could not find a lesion to show the owner. The difficulty to him was that in every county the inspectors were working under different conditions. If all inspectors were put under one heading, and one scale of fees, they could combine, as Mr. Toope wished. Where local authorities paid different fees the difficulty was to get a working basis. He greatly feared that the whole of that business would be centralised in the Board of Agriculture, whole-time inspectors being employed, and if that were so the local veterinary surgeon would not get a chance. (Hear, hear.)

Mr. MALE. Personally, he thought there were two things in the working of the Order as to which there still appeared a considerable amount of doubt—one valuation, and the other the scope of the Order. As to the former, in many cases that had been brought to his notice, the amount obtained after slaughter, *i.e.*, the salvage, had been more than the owner had had, and naturally the owner kicked against that. He himself, instead of working from the top to the bottom, worked from the bottom to the top. If an owner only got quarter value for a diseased animal, they should work up from that 30/- so that in the event of the animal being found on post-mortem not badly affected, he would get at least three times 30/-. Where a carcass had made £6, £7, or £8 it was obviously unfair, and brought disrepute on the Order as well as on the valuer if the owner only received 30/-. He thought the Order justified them in treating values in a more liberal manner. (Hear, hear.) To pay compensation £60,000 was set aside every year; and for the first nine months only £4,000 to £5,000 had been utilised, so that people who had those unfortunate cows might surely be treated a little more liberally. He quite agreed with Mr. Seldon that they should press for the one valuation; for neither the local authorities, the police, or the valuers themselves understood the two valuations. That one valuation should, in his opinion, be the *market value* of the animal as it stood, and he would let the owner have either three-fourths or one-fourth of this value; and £1 besides the full value if the animal proved to be not affected. Most of them, he thought, had made mistakes as to what cows were really included under the Order. They were only able to deal with cows that were emaciated or were giving tubercle bacilli in the milk, or had tuberculous udders. If they attempted to deal—as owners often wished them to deal—with animals that were not emaciated it complicated matters very much. In the case of a cow suspected of giving tubercle bacilli in the milk it was sometimes necessary to inject guinea-pigs, which meant that the cow and the milk had to be “hung up” for a month until the test was completed. In such a case he thought the owner should be paid fully for the milk that had to be destroyed during that period. (Hear, hear.)

As to compulsory inspection of markets, there were a lot of markets that were not inspected, and to make the Order complete he thought veterinary surgeons should press the Board to compel all local authorities to have their markets inspected. (Hear, hear.) The heavy cost of the administration of the Order had been borne by the local authorities, and did not come out of the Exchequer at all. Farmers naturally kicked against bearing the enormous expense that involved, and getting no help from the Treasury, and they had petitioned the Board of Agriculture to put three-fourths on the Treasury, and in that they should receive every support possible. When the question of fees was first discussed he thought that the fees should not be excessive, although they should be adequate. Mr. Slocock suggested that the authorities might consider the fees too high, but he thought the fees they charged at present were the extreme minimum. If veterinary surgeons stuck together he thought every county would adopt

the National scale, as most counties had done. (Hear, hear.)

Mr. WILLETT wished to compliment Mr. Slocock on his comprehensive and admirable opening of the debate. (Hear, hear.)

Mr. PARKER said he, as an inspector, had never condemned a fat animal brought to market if evidently in good general health.

Mr. TOOPE said his greatest difficulty had been with regard to valuation in cases of tuberculous udder. He was pleased to hear Mr. Slocock touch upon the question of miliary tuberculosis, which he had not the slightest doubt was a most dangerous form, as in all such cases infection of the blood stream had occurred; all such cases he should certainly condemn. (Hear, hear.)

The PRESIDENT said he could not see where the great difficulty came in over valuation. It was very clearly laid down in the Order, but they must not confine themselves to the Order only. Under Article 6, the first valuation (health) was simply for the purpose of giving the authority deciding compensation some idea of the animal they were dealing with; the second was simply whether the beast was tuberculous, and if it had a tuberculous udder in so far they would delete from the value of the cow as a milking animal. If on post-mortem nothing was found wrong but the udder, the cow would be fit for human food, and that had to be considered in the valuation as well as the disposal of the milk. The difficulty arose if they did not look at it in that light. He did not think the valuer should be expected to assume to what extent the animal was affected. When very emaciated, cows had only one value practically—knackers' price. Mr. Coleman then dealt at length with the conduct of the police in his district in the matter, and read correspondence. Proceeding, he said he quite endorsed what Mr. Slocock had said as to the number of tuberculous animals going into London. He took a public health point of view of that and felt that if in the remedying of one evil they caused another it was a very serious thing. (Hear, hear.) The longer he lived the more difficulty he saw in separating the public health department of their profession from the Board of Agriculture. (Hear, hear.) He had been given to understand by some people who knew that the present Order was practically a start, and that it was hoped in time to considerably extend it.

Mr. PARKER discussed the peculiarities of the tuberculin test.

Mr. MALE related some interesting experiences in connection with some large herds he had tested.

THE INTERIM REPORT ON SWINE FEVER.

The SECRETARY had hoped to give a review of the second Interim Report of the Departmental Committee on Swine Fever, but time did not permit.

SPECIMENS OF INTEREST.

Mr. PARKER showed a number of new obstetric instruments.

A large number of morbid specimens were exhibited, including:

By Mr. Broad: Retropharyngeal glands from a cow and very fine specimens of double odontoma he had removed from a horse.

By the President: A very large piece of bone—which had caused death—taken from near the cardiac orifice of stomach of bull-dog; also some specimens of *strongylus tetracanthus*.

The PRESIDENT accorded the thanks of the meeting to Mr. Toope, Mr. Slocock, and Mr. Parker for his demonstration, and the gentlemen who had brought specimens.

Mr. PARKER replied.

At the close of the meeting tea was provided at the kind invitation of Mr. J. H. Parker.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

THE YORKSHIRE
VETERINARY MEDICAL SOCIETY.
[NATIONAL V.M.A.—NORTHERN BRANCH].

A meeting of the Society was held at the Hotel Metropole, Leeds, on Friday, the 24th April, at 4 p.m., when the Chair was occupied by the President, Mr. J. Abson, of Sheffield, and the following members were present: Messrs. S. E. Sampson, Sheffield; M. Robinson, Barnsley; A. Ellison, Harrogate; J. A. Dixon, S. Wharam, H. G. Bowes, A. W. Mason, Geo. Barber, Leeds; Thos. Pratt, Ripon; Hy. Sumner, Liverpool; S. B. Vinc, Settle; F. W. Pawlett, York; H. W. Holland, Keighley; P. R. Thompson, Halifax; J. S. Woodrow, Swinfleet; J. A. Hodgman, Barnsley; Geo. Whitehead, Batley; C. Pitts, Bradford; J. Clarkson, Garforth, hon. sec.; and A. McCarmick, Leeds, hon. treas. Visitor: Mr. Jas. Douglas, Ripon, Pharmacist.

Apologies for absence were received from Prof. Bradley, Messrs. Lloyd, Bowman, Lazenby, Weston, Pollard, Crawford, and Somers.

The minutes of the last meeting were taken as read.

The SECRETARY read correspondence from Mr. Shipley, of Great Yarmouth, asking for financial support towards the Victoria Veterinary Benevolent Fund, which was established for the purpose of affording help to the necessitous widows and children, particularly of young veterinary surgeons who had died before being able to make proper provision for their dependents.

In reference to the resignations which had been received from three members of the Society, the Secretary stated he had written the three gentlemen in question, as empowered at the last meeting, asking them to

reconsider their decision, but up to the present had received no reply. He asked permission to write them once more and make another attempt to get them to retain their membership. This was agreed to.

MOTION BY MR. S. WHARAM.

MR. S. WHARAM moved the following motion which he had given notice of at the previous meeting:—"That the word 'medical' be deleted from the title of the Society." He remarked that it was probable the dictionaries at the time when the word "medical" was inserted were not the same as at the present date, otherwise he could not understand how the word became inserted in the title. The word "veterinary" to-day meant the art of healing the diseases of domestic animals, whilst the word "medical" simply meant the art of healing. The two words together savoured somewhat of tautology, and were simply a duplication. However, in the wisdom of the Society it had been decided about 12 years ago, apparently he supposed for simplicity's sake, that the title of the Society should be the "Yorkshire Veterinary Society." Shortly afterwards the word "medical" was reinserted, but there was reason for that change. It was imagined that as registered medical practitioners they might thereby obtain exemption from acting on juries and rebates in the motor taxes and the duty on petrol. They were all aware that their desires in that direction had not been fulfilled, and never would be. None of them, he thought, wished to ride on the backs of the medical profession and receive concessions in that way; if they were to receive any concessions at all they wished them to be granted to them as veterinary surgeons and in no

other way. That was one of the reasons why he suggested they should call themselves the "Yorkshire Veterinary Society." Such a title would signify that they were a society of veterinarians quite unconnected with the medical profession, though at the same time it did not distinguish between veterinary medicine and veterinary surgery, as he considered those two distinct branches of their own profession. In the interests of the Society and of the profession he thought it would be a wise thing to strike out the word "medical" from the title.

The CHAIRMAN seconded the motion. In his opinion they could quite well do without the word "medical," which seemed to him somewhat to trespass upon the domains of the medical man, though he did not know whether the medical profession viewed it in that light at all. He thought they were quite capable of standing on their own bottom. The original title of the Society had been the "Yorkshire Veterinary Society," and it was altered because it was thought by doing so they might obtain the concessions suggested by Mr. Wharam, but as the change had not brought about the results anticipated, he thought without any qualms of conscience they could now dispense with the term "medical."

The SECRETARY announced that he had received a telegram from Mr. Lazenby who was not able to be present, stating that he regretted his absence as he would have voted against any change in the name of the Society.

Also another communication from Mr. Pollard regretting he could not be present at the meeting as he had hoped to assist in defeating Mr. Wharam's motion. "The founders of the Society," he thought, had good reason for including the word "medical." They were getting into closer touch with the medical profession every year, and he saw nothing to their disadvantage in including the term in the title, especially as, under the name of medical practitioners, they were endeavouring to obtain the same privileges as were accorded to their sister profession, namely, the rebate on the petrol tax and exemption from service on juries. He could not see any possible gain in such a retrogressive step."

Mr. BOWES rose to a point of order, and asked whether a motion of that kind for the alteration of the title of the Society should not be discussed at the annual meeting, and three months notice be given before such annual meeting.

Mr. McCARMICK said the same question had been brought up the last time the rules were altered, and it was stated it had been a mistake.

The SECRETARY said the history of the whole matter was that when the rules were revised it was suggested by the Committee of revision that the word "medical" should be dropped. The rules were examined by the members and were passed practically as a whole. Later on, apparently, some of the members had noticed that the word "medical" had been dropped, and on the subject being discussed a resolution was carried that the name of the Society should again be the "Yorkshire Veterinary Medical Society." He would like to point out at the same time that the title of the Society did not comprise one of the rules.

The CHAIRMAN said he would rule that it was not a rule and that the notice suggested by Mr. Bowes was not required.

Mr. BOWES said that that being so he would certainly oppose Mr. Wharam's motion. They were practitioners of veterinary medicine and veterinary surgery, and though to give the Society the full title of the "Veterinary Medical and Surgical Society," would be unnecessarily wordy, yet he did not see why the word "medical" should be dropped. Other societies of a similar kind were called "Veterinary Medical Societies" and he thought it was a more correct designation to retain the word "medical." Veterinary medicine was a branch of

medicine, and they were not in any way trying to usurp any medical title in using the word. They could claim to be one of the branches of the great profession of medicine, and as such they might ultimately enjoy some of the advantages of the medical profession.

Mr. SUMNER supported Mr. Bowes. He was present at the meeting when the word "medical" was adopted, he said, and while he recognised that it was possibly adopted at the time for selfish reasons he thought they were entitled to it. He was conscious of a certain feeling animating the rank and file of the profession which was antagonistic to the medical man, as it was felt that in the matter of public offices and administrative control the medical man was "top dog." He himself, however, did not share those feelings, because in the matter of public health the veterinary man represented the type of animals that the public authorities had to deal with, and the diseases of those animals which they were endeavouring to mitigate.

Mr. BOWES again rose to ask whether the matter was strictly in order, because although the title of the Society might not be embodied in the rules it was included in the preamble to the rules.

The CHAIRMAN said it would be much better to dispose of the matter at once. He himself had seconded the motion, but he had done so more with the idea of bringing about a discussion and settling the subject once for all.

The motion was thereupon put to the meeting and declared lost.

The CHAIRMAN: We will take it as a substantive motion if you like, Mr. Bowes.

Mr. BOWES: I am satisfied.

In regard to the Hunting Memorial Fund, the Secretary stated he had received a letter from Mr. Carter, the President of the Royal College of Veterinary Surgeons, enclosing two forms of petition to the First Lord of the Treasury that pensions might be granted to the children of the late William Hunting, and asking that the matter might be placed before the meeting so that a resolution might be passed authorising the Chairman and officers to sign and return the petition. The Secretary pointed out that the matter had been considered at the Council meeting, and the Council recommended that the President and officers of the Society should sign the petition for presentation to the Prime Minister. This was agreed to.

The SECRETARY also stated the Council had considered the question of making a subscription towards the funds required in connection with the International Congress and in addition had recommended that the President be appointed as the delegate of the Society.

Mr. A. W. MASON proposed this recommendation be confirmed, and this was carried.

SOME CLINICAL EXPERIENCES.

Address by H. SUMNER, M.R.C.V.S., Liverpool.

Case 1. A thoroughbred mare which was served in the early months of the year and, becoming pregnant, was sent to the part of the world where he lived. During the back end she slipped twins and held her placenta; this was removed, and there was no difficulty with the womb. She returned to Newmarket for stud purposes again and was served rather sooner than he considered advisable, as he had thought it would be well to give her several months rest. The mare afterwards was sent to Liverpool again, and up to November looked as well as any mare in the stud. About November he was called in to see the mare, as it was stated she had been doing badly. He thought she might have become somewhat dirty inside and ordered her some sloppy food, but he did not think it relieved her. The mare stood with her behind against a wall for shelter, her coat was erect, she looked wretched, miserable and

dejected. The pulse, however, was normal, and she had no temperature. Inspection of the excreta was made and it was found entirely satisfactory, but on looking at the buccal membrane and mouth he found it foul. On getting closer he noticed that she had cast her chestnuts which had peeled off. The mare was taken to another place away from the other mares. He suggested the probability of pick foaling, and instructed the groom to watch for foetal movements. Continued and increasing cutaneous irritation was noticed in the limbs, the nose, the ribs, the face, but there was no temperature. Appetite failed generally, especially in the morning. Probably in the early afternoon the mare would begin to nibble a bit, and she might take her evening meal. These symptoms continued, and about Christmas time it was seen that failure was coming about pretty quickly. There was no uterine evidence and there was no reason to believe that the foal was vigorous. The mare eventually became emaciated, got down, and died. The prominent feature of the abominable buccal membrane was a symptom which he would not easily forget.

During this time the owner became alarmed because the mare did not pickfoal, and it was thought she was suffering from poisoning from a dead foetus. Alarm was also felt as to whether it was not something infectious, but he was able to satisfy the owner on that score. He gave the opinion that the mare was suffering from the reabsorption of a poison which was generated in her own body probably of a uterine source. The death was the usual toxic death; she became unable to rise and so died. She was not shot.

In the post-mortem a most extraordinary condition of the stomach was found. It was suggested when she did not pick that she was probably doped. The fashionable dopes—arsenic, antimony, nitrochloric acid, nitroglycerine, were well known, but when the contents of this mare were analysed the chemist found, curiously enough, an excess of zinc. He (Mr. Sumner) had never known zinc in any shape or form to be used as a dope, and incidentally he would be very glad to know if any gentleman present were able to say that he knew of zinc being used for that purpose.

The foetus had died probably a few days before the dam; there was a little bit of detachment from the dam. It seemed to have been arrested and was only a miniature foetus, but it was not a dead foetus nor foetid. The stomach was the root of all the evil. It was the most extraordinary thing he had seen, particularly in the cuticular portion. In the villous portion he felt a difficulty in describing it; in the fresh state it looked as if swollen, rigid, corrugated, and raw, but on the surface it was covered with certain epithelial cells. The liver was enlarged, and the main and subsidiary ducts were wholly hypertrophied. The stomach was passed on to the pathological laboratory of the Liverpool University where it formed a very interesting object of study, and the consideration of its pathological condition had not yet been completed. The first report obtained from the laboratory in February, stated that "the section of the cardiac end of the stomach shows very marked inflammatory fibrosis and thickening of the mucous coat, proliferation of the superficial epithelium which in places is becoming epitheliomatous. The sections of the liver show that the cysts are composed of dense fibrous tissues. The condition of the stomach, which is most unusual, has evidently been due to some continued chronic irritation which has been acting for many months. There is no evidence that the irritant was a chemical one." The Professor adds: "If I had known you intended to show the case I would have given you a longer report. I think it ought to be published eventually. Since writing the report, I have found certain small collections of multi-nucleated cells whose arrangement is such that they suggest parasitic

infection, but I have not succeeded in demonstrating the parasites. Chronic irritation leading to epithelioma is well known in human pathology, but I have no record in animals."

The curious feature of the case was the entire absence of temperature. There was the persistence of this abominable condition of the buccal membranes the whole time, but there was practically no evidence of pain. The owner was informed that the result of the analysis showed an undue proportion of zinc, and he immediately suggested it might be attributable to the fact that the drinking troughs in the paddocks were lined with zinc. This, however, was a mare out of a stud of 30 which were all under the same conditions, and the drinking water was from the corporation water supply, pretty well charged, as usual, with lime, and there was no evidence of it causing a solution of zinc in any great quantity.

At the last Liverpool Assizes a firm of chemical manufacturers was sued for the loss of some sheep which were said to have died through drinking water which had been poisoned by the fumes and effluents from their works. It was found that zinc was present in the dead sheep in unusual quantities, but curiously enough the defendants were able to produce analyses of sheep and other animals from other places far afield which showed quite as much zinc, and in some cases more.

Case 2. Mr. Sumner had been called in in consultation in Cheshire. He asked the owner to describe the case, but was told that the cases were of all kinds. Some of the cattle appeared to be in for pneumonia, others foundered feet, others nervous disorders, others queer on their legs. Some of the animals were attacked with curious periods of increased respiration, which passed off in 36 or 48 hours. At the same place a year before a similar trouble had arisen when the animals had been brought into the homestead. In investigating the cases to find out the cause Mr. Sumner considered the hygiene, the dietary, and practically everything possible, but could not lay his hand on any particular source that was likely to bring about the particular pathological condition. Finally the water was tapped. This was obtained from a borehole, zinc and lead pipes, and stood in a red sandstone reservoir, and some of the water was even used in the house itself. The water supply was stopped and for a time pit water was used. When the water was analysed it showed an enormous proportion of zinc, and fortunately the trouble ceased to exist when the animals went off the water. In view of the loss of the valuable mare previously mentioned, and of the trouble with these sheep and cattle, it did seem to him as if zinc might be a much more serious poisoning agent than many of them would have believed.

IRREGULAR DENTITION.

Those interested in equines, and especially heavy breeds, had all had trouble in adventitious molars, he remarked. The trouble he had himself experienced was with a seventh molar on the lower jaw; he had never come across a seventh molar on the upper jaw which had seriously interfered with the ability to take food. A great trunk of a horse gradually declined, and came to have his mouth examined. No irregularity was found in his teeth and no spaces; his teeth were rasped over, and he was given tonic powders and sent off. But he only went to come back again, there was no relief, he mauled his food and turned it out in pellets. The muscles of his face and lips were found to be alright, and prehension was alright, nothing was found wrong with the palate, nor with the fauces, but right at the top this extra molar was coming down. The horse became emaciated. He was fed on slops until he got tired of them, and the owner came to the conclusion that something would have to be done. Mr. Sumner described to him the difficulty of getting sufficient power at the end

of the mouth to extricate the tooth, and suggested taking the sixth molar out, as he might not be able to get the seventh, and in the hope that the seventh molar would fall in the place of the disused sixth. This was accomplished and the sixth tooth was taken out, and then the seventh. There was a small mark of attrition on the seventh molar where it had come into contact with the opposing sixth, which was worth looking at. The seventh molar on the other side could not be got out, and the horse remained with the seventh molar on his off side. Since this operation the horse had been eating well from that time.

CORONET LAMENESS.

Mr. Sumner went on to put the question whether they would have to recognise that equines suffered from pyrrhœa or alveolar periostitis?

In heavy city practice he thought they would agree with him that sometimes the ricketing of the coronet was one of their greatest difficulties. It was frequently a blind lameness, frequently very intense, and frequently very difficult to treat. Very few cases made rational recoveries. Perhaps only within comparatively late years he had come to the conclusion that most of the ricketed coronet pedal joints were not ricketed so much, but rather that they resulted from arthritis which was due to some interference with the pyramidal process of the pedal bone.

The specimen he showed was the off-hind foot of a mare which had a quitter on the inside. He had operated upon her in the stocks as he could get a fairer cutting by that means than on a table or on the ground, and he had not given a general anæsthetic but had given an injection. Having exposed the necrotic tissue she was packed up and sent home. Everything seemed satisfactory, she was not lame, and the wound appeared to be doing very well. She afterwards went lame, however, and the trouble got worse. The owner thought it was due to something arising out of the operation, and he (Mr. Sumner) thought—had he infected something? Was his needle not sterilised, or the drug he used become effete? The ordinary surgical dressings were removed, and in about a fortnight there was some little enlargement just over the anterior part of the coronet rather to the inner side, and the whole time the mare avoided putting any weight on the foot. This gradually developed until it liquidated, and there was considerable hæmorrhage. The owner did not say "kill," and Mr. Sumner did not. She lived so long that the stuff she was standing on gave way, in fact the pedal bone came down. In the end she was put down, a dissection was made, and the hoof was taken off.

From the specimen it would be seen that the pyramidal process was fractured in several portions, and there was one loose portion on the top. The lameness in this case was not an immediate lameness, but a progressive lameness. No injury was caused in bringing her leg up on to the stocks which might have accounted for the fracture of the bone. How that fracture originated remained a puzzle.

Another case Mr. Sumner mentioned, was a mare discovered lame and put into a forge to have her foot examined. A little humidity was found and the smith thought it was "thrush." The foot was put into a bag, but shortly after the mare was found to be painfully lame. The lameness was persistent, acute, and extreme. The mare put no weight on the limb; she was not pointing and snatching the limb up, but stood on it persistently and would not move it voluntarily. It was suggested to the owner it was a serious case. She was a mare in disagreeable health, had a greasy heel, and was nine or ten years old perhaps, and had a discharge commonly called the "whites." She was a good sort of mare but not a good resistant. In time the affected leg became œdematous, and then the other leg also. Eventu-

ally she was put down. In the specimen it would be seen that he had removed the horny box. The matter was not delayed until the mare showed necrosis of the part affected, but it was decided it was a bad case, and she was slaughtered. In this case he (Mr. Sumner) tried to find a fracture of the pyramidal process; he had held the foot on his knee and had tried in many ways to find whether he could get any direct or indirect crepitation, but had failed. From the section they would see the attachment to the pyramidal process was quite broken off and was going through some necrotic changes. The pyramidal process represented a very definite laceration, and behind the coronal pedal joint would be found all the evils. He thought probably there was more acute pyramidal disease than they were conscious of.

On the subject of dairy cattle, Mr. Sumner mentioned he recently had three recurrences of dropping within 12 hours after apparent recovery, in one particular place. The beasts were down with typical symptoms of milk fever. Inflation was made, and in six hours they regained consciousness, recovered the use of their legs, and every appearance of health, but 12 hours afterwards they were down again. He did not want to touch on the pathology of milk fever, but he should like some information as to whether in the practices of the gentlemen present they had reason to believe that leaving the udder tense after calving was any preventive against milk fever. Until recently, in his own practice when consciousness was restored he had been anxious to get the udder clean, with the idea that it would wash away or bring down something which was apparently causing the nervous disturbance. There were a good many observers who did not quite believe in the presence of autogenous toxin in the udder.

Mr. Sumner then introduced the subject of epizootiology. He had a client, he said, who had a big establishment of coursing dogs. Those who knew the habits of coursing dogs would know that when the saplings were brought into the training quarters it was generally necessary to look out for some kind of disease, as they might be germ carriers, convalescent of distemper but still able to infect other dogs with which they came in contact. This particular outbreak he had no hesitation in saying was the dog typhus or what was known as the Stuttgart disease. The owner came to the conclusion that the kennels must be reeking with infection and he suggested that they should be thoroughly disinfected under his (Mr. Sumner's) direction. But Mr. Sumner suggested that it was not merely disinfection of the kennels that was required but new kennels as the present kennels could only be called dog dungeons. There was no light and the air space was not good. The kennels were long narrow compartments 15 feet high with a little window that could be opened. The roof came about 14 feet and then was cut up at an angle. There was no light, and what little ventilation they got was through the door. The trainers believed that the dogs should be hard worked and put in a place without any light either from the walls or from the sun, and that they should be kept in the dark, and he had to get over that sentimental idea. Mr. Sumner suggested a certain vaccine, which had been put on the market for the prevention of canine distemper, might be used upon one half or two-thirds of the dogs, and the owner agreed to this. Twenty dogs were inoculated and one kennel was altered. All went quite well and the owner was so pleased with the results that he ordered 40 more sets of the vaccine and said he would have them all done the week after the Waterloo Cup when so many saplings would be coming in. Just before the Waterloo Cup, however, the owner reported that several of the dogs were queer again, and they had to vomit them and purge them, as they were not getting the stuff out of their stomachs, and their vomit was found to be full of bile. When Mr. Sumner asked

to see how the dogs were vomited he was given a demonstration with a lump of washing soda about as big as a hazel nut. The stools of these dogs were not quite right, but they took what food they got. He suggested that the dogs for the Waterloo Cup should be removed, and this was done. When the saplings came in he suggested that they should not come into the kennels but should be drafted into another centre and inoculated before they were introduced, for fear that this indefinite disease might be a low form of infectious disease; but the difficulties of arranging separation were too great. The buildings were sprayed with Izal. Twenty-six dogs were inoculated, and in addition the other dogs in the other ranges of kennels that have been mentioned. In the meantime the dogs from the Waterloo Cup came back, and they remained well. The trainer then reported that every dog was sick, both those that were inoculated and those that were not. Whatever was the cause, the trouble has gone on; the older dogs which were fairly resistant have not been much trouble, but all the fresh dogs have had what would be called a gastro-enteritis. The trainer's opinion was that it was due to a blockage in the bowels. A post-mortem was made on one bitch which died, and it was found to have an intussuscepted gut; another had a very acute and hæmorrhagic pneumonia. The question arises, is it distemper in one of its manifold forms? Afterwards when other saplings came in they were taken to another establishment. They were neither fasted nor wormed, but two days after they came in, all in apparent health, they were submitted to inoculation, and at the end of a week it is presumed that immunity will have been acquired—if it can be acquired by this means, and these ten saplings will then be put into the same kennels with the others where this particular disease is ravaging. So that perhaps upon another occasion, said Mr. Sumner, I shall be able to tell you whether these ten dogs by reason of their inoculation have been able to resist the disease.

It was decided that the discussion on the address should be adjourned until the next meeting in July, when it was hoped Mr. Sumner would be good enough to attend to reply on the points raised.

The CHAIRMAN moved a hearty vote of thanks to Mr. Sumner for the excellent address he had given them, and which he characterised as very much more interesting than a set paper. This was carried with applause.

Under the heading of "Interesting cases" Mr. Whitehead instanced a case of a horse suffering from prolapsus ani such as he had not seen for something like 20 or 30 years.

Mr. CLARKSON inquired what had been the result of the case.

Mr. WHITEHEAD: Entirely successful,

Mr. CLARKSON: What was the treatment?

Mr. WHITEHEAD: Holding it back. A man was employed holding it back for a day and a half.

Mr. ELLISON said he had had a similar case to Mr. Whitehead's, and he had supplied a truss which had proved effective.

Mr. SAMPSON said he would like to ask Mr. Sumner's advice upon a question of pigs, as he knew he was a great authority on them. During the last two months he had come across 18 or 20 cases of sows with their first litter going four or five days or even a week past their time, and developing fits, and either dying quickly or parting with one or two pigs and then dying afterwards, some with pigs and some without. The post-mortem showed absolutely nothing macroscopically except in their lungs, where he had seen pretty constant hæmorrhagic patches, but all the other organs so far as one could see were quite healthy. Perhaps the President could say whether he had been called in to see any cases of swine fever in his (Mr. Sampson's) district.

The CHAIRMAN said he had been called in to several cases referred to by Mr. Sampson, and had been quite at a loss to account for death. He had to return such cases as "obscure," all the organs appeared apparently normal.

Mr. CLARKSON said he had had similar cases in his practice, and in some cases a modified ailment of the same type which led up to paralysis, those which recovered from the fits ending in paralysis. He had made two or three post-mortems but had not been able to find anything. He would suggest a toxin.

The CHAIRMAN expressed the thanks of the Association to Mr. Pratt, one of the founders of the Society, and the donor of their collection of horse shoes and other veterinary specimens, for his attendance there that afternoon. They were very pleased to see him once more amongst them, and congratulated him upon the marvellous recovery he had made from his recent illness. He hoped Mr. Pratt would view with satisfaction the provision the Society had made for the collection he had so generously presented to them.

Mr. PRATT briefly replied.

Mr. MCCARMICK proposed a vote of thanks to the President for his services in the Chair, and on being seconded by Mr. Wharam, this was carried unanimously.

J. CLARKSON, Hon. Sec.

"Localised" Tuberculosis in the Pig.

A report made to the Local Government Board by Dr. A. Eastwood and Dr. F. Griffith, issued recently, gives the results of a valuable series of observations on the distribution of visible tuberculous lesions and of tubercle bacilli in pigs selected at the slaughterhouse as examples of minor degrees of pig tuberculosis. The term "localised" tuberculosis is often loosely used in meat inspection, but it is used in this report to signify disease which as naked-eye examination is apparently confined to the lymphatic glands in relation to the alimentary tract. Among the ordinary pigs which come to the slaughterhouse, tuberculosis actually localised in this way is much less common than tuberculosis which is more or less widely disseminated. Thus at the Brighton abattoir, from which a large part of the material was obtained, 24,144 pigs were examined during the period of selection, of which 209 were reported by the meat inspector to be affected by general tuberculosis, 393 had slightly disseminated tuberculosis, while localised tuberculosis was present in only 59. The pig, as the work of the Royal Commission on human and animal tuberculosis showed, is susceptible to infection with various bacilli of mammalian type (including bovine and human) and with avian bacilli. By far the most common source of infection is the bovine, derived from tuberculous milk or from the tuberculous faecal discharges of cattle; but avian infection may also arise from ingestion of the excreta of fowls, while in one or two of the series reported on, the bacilli were found to be of the eugonic type, of low virulence for rabbits, indicating a human source of infection. Avian infection in the pig appears to have much smaller tendency to dissemination—when judged by the presence of naked-eye tuberculous lesions—than bovine infection. Generally, when infection was due to avian bacilli the affected glands were either not enlarged or only slightly so; they contained gritty or calcareous nodules which were easily shelled out of the surrounding tissue, leaving behind smooth fibrous-walled cavities. With bovine infection, a greater degree of local gland affection was apparent, and when closer examination was made in the laboratory of lungs, liver, spleen, and certain other tissues of the pigs classified in the slaughterhouse as examples of "localised" tuberculosis, naked-eye evidence of dissemi-

nation was frequently found. Of the 59 pigs above referred to, for example, the disease was ascertained by this special examination to be strictly localised only in 24. In regard to the presence of tubercle bacilli in apparently normal organs and tissues, it was noteworthy—and reassuring in view of the comparative harmlessness of the avian bacillus to man—that the bacilli were readily found in tissues presenting no naked-eye lesions when avian infection was in question, but very seldom in the case of bovine infection. In one or two instances the examination of the tuberculous lesions of the pig demonstrated the co-existence of mammalian and avian bacilli, or of different kinds of mammalian bacilli, in the same animal. The Royal Commission of 1896 recommended that the whole carcass of the pig should be regarded as unfit for food if tuberculosis was present in any degree, and their finding receives some support as a result of these investigations. In practice, however, the recommendation has often been considered too drastic to be generally acted upon, and various modified standards of condemnation have been adopted. It may be concluded from the report that where partial condemnation is practised it is important that the examination of the carcass and its organs at the slaughterhouse should be thorough, so that the extent to which the animal is affected can be accurately gauged.—*The Lancet*.

Tuberculous Cattle—A Tall Order.

The cause and prevention of tuberculosis in infancy formed the subject of the first of a series of lectures delivered, under the auspices of the Glasgow Infant Health Visitors' Association, at Glasgow University on May 7th. Dr. Leonard Findlay, the lecturer, said a great deal of the disease in infancy and childhood was due to infection from the cow. There was absolutely no reason, he said, why they should not rid the country of all tuberculous cattle. Were the Government to order the destruction of all tuberculous cattle, and make it illegal to keep milch cows of more than five or six years of age, bovine tuberculosis would cease to exist.

It had been stated in Parliament recently that there were 80,000 tuberculous cattle in Britain. That represented £1,600,000 at £20 a head, or only about one-half of the cost of a warship. At present the Government made a grant of £1,500,000 for the erection of sanatoria simply for the treatment of the disease.—*Glasgow Evening Citizen*.

The V.S. in S. Africa—An Appreciation.

The following is taken from the Official Souvenir of the South African Industrial Exhibition held in February, 1914, at Cape Town:—

"Probably no technical man has borne so much opprobrium, received so much opposition, or been the subject of so much banter, yet pushed on more doggedly, than the veterinary surgeon. Fortunately there was one prominent figure whose industry, capability, good work, and good humour always stood out clearly enough to convince those who could see that if there was failure at any time was due to individual and not to the cause. To-day, still, there are those—a good many—who have no friendly feeling towards a veterinary surgeon. Men whose freedom has been restricted on account of the prevalence of some disease or another are not always philosophers. Men who have to apply restrictions are seldom regarded as friends; and sometimes, we must admit, restrictions were not wisely enforced, though the intention was excellent. But the veterinary surgeon has, in the end, won his way, if not to the affection, at any rate to the intelligence of the great majority of the people. It is a long story to deal with the various remedies that have been discovered or

introduced—and here we must include the bacteriologist—but we should at least mention the cure of wire-worm and the geilziekte in sheep; inoculation against rinderpest, redwater, lung sickness in cattle, against blue-tongue in sheep, and against horse-sickness in equines, and the treatment of ostriches for internal parasites. The discovery of the greatest practical value, however, has been the effect of dipping cattle against ticks. It was a farmer who first proved this, but again science had to come to our aid, first in giving us the life history of the various ticks, without which dipping would not have received half the credence it has, because it would often have been wrongly applied, and secondly, in giving us the most suitable formula. Dipping has deprived East Coast fever of its power to decimate, is making cattle farming more profitable, is helping to increase our herds at a greater rate than formerly, has enabled us to restock with sheep whole districts which were less than a decade ago denuded of small stock by heartwater. It is often said that no country is so subject to diseases of domestic animals as South Africa is. If so, it is a tribute to the scientists employed in connection with them that the number of live stock has increased so largely."

DISEASES OF ANIMALS ACTS, 1894 TO 1911.

Return showing the number of Premises on which the existence of TUBERCULOSIS has been notified to the Board of Agriculture and Fisheries during the month of April, 1914.

* Number of bovine animals suffering from tuberculosis of the udder, tuberculosis with emaciation, or giving tuberculous milk, in respect of which notice of intention to slaughter has been received.

PARLIAMENTARY.

MILK AND DAIRIES BILL.

In the House of Commons on Tuesday, May 12th.

Mr. HERBERT SAMUEL: The general law had had regard chiefly to the prevention of fraud and adulteration, and but little regard to the more important matter of the protection of public health. Expert authorities had reported that tuberculosis among children was undoubtedly spread by the consumption of tuberculous milk, and the Royal Commission on Tuberculosis, which sat for six years, and the recent Departmental Committee on Tuberculosis, presided over by the hon. member for Plymouth, reported unanimously in the same sense. There were in England and Wales 53,000 cases of tuberculosis every year, of which one-fourth were non-pulmonary, and a considerable proportion was due to the consumption of tuberculous milk. About 100 local authorities had now secured power to protect their population against contaminated milk. They were almost all urban authorities and the result was the multiplication of inspection in rural districts which was most distasteful to the agricultural industry. (Hear, hear.)

It had long been recognised that the matter demanded legislation, but the subject has proved a matter of heated controversy. Several great and powerful interests were concerned. The public health authorities, especially in the towns, were properly eager to safeguard the health of their population and unwilling to surrender the powers conferred on them by local Acts unless they were assured that a really efficient system of inspection and control would be established in rural districts. The milk-selling industry, a numerous and highly-organised body, which was conducting a trade of inestimable value to the community, were anxious to secure the purity of the milk supply, but did not desire that in the conduct of their business they should be unnecessarily harassed by regulations. They were especially anxious that they should not be punished for faults that they had not committed merely because they were the parties most easy to reach. (Hear, hear.) Thirdly, there was the great agricultural industry, equally eager to observe any practical measures to maintain the reputation of the milk industry and safeguard the public health, but objecting strongly to the present system of multiple inspection and timid lest they should be exposed to harassing and unpractical regulations framed by persons who had more regard for urban considerations than knowledge of agricultural interests—idealists who endeavoured by a stroke of the pen to make all cowsheds on the farms model dairies.—(Hear, hear.)

He had attempted to frame a Bill that would meet with the general assent of the parties concerned. It was necessarily of a detailed character, but, generally, it proposed to make regulations to prevent the supply of contaminated and dirty milk. Those regulations would be made by the Local Government Board with the concurrence of the Board of Agriculture and would be laid before Parliament and would not become operative if either House passed an Address against them. He was taking every step to prevent unreasonable regulations being made by any Government Department. They proposed to provide means for tracing diseased milk back to its source and stopping that source. Where there was adulteration the Bill enabled improved procedure to be adopted to bring the offence home to the really guilty person. (Hear, hear.) It abolished the present system of multiple inspections and provided a single inspection. It applied similar precautions to foreign milk imported for consumption. (Hear, hear.)

It did not deal with any question of finance, but the Board of Agriculture proposed to compensate farmers for cows that had to be slaughtered on the farm on a more generous scale than hitherto. (Cheers.) The public health grants in the Chancellor of the Exchequer's Budget would provide for paying half the salaries not only of medical officers of health and sanitary inspectors, but of veterinary surgeons and milk inspectors. He would gladly consider any suggestions that might be made. For five years Bills on this subject had been brought before Parliament. He trusted that this Session Parliament would be willing to deal by general assent with a subject which admittedly demanded attention.

The Bill was brought in and read a first time.

REVIEW.

MÉDECINE CANINE, par P. J. CADIOT et F. BRETON. 3me Ed., Small 8vo., cl. pp. x. + 372. With 69 illustrations in the text. Six francs. (Asselin et Houzeau, Place de l'Ecole-de-Médecine, Paris.)

This book really should have been called a "Canine Medicine and Surgery"; for its subject matter comprises almost if not quite as much surgery as medicine.

It is divided into two parts. The first numbers 302 pages, and treats chiefly of the diseases of special organs or sets of organs, including not a few surgical conditions. Close upon fifty pages are allotted to infectious diseases; and the last forty pages deal with "diverse surgical affections." For the most part the last-named portion consists of the general principles of treatment of wounds, abscesses, hernias, fractures, dislocations, etc., with some detailed consideration of a few special conditions.

The second part of the work deals altogether with surgical operations. Rather more than thirty are included, the technique of each being briefly but clearly described. Most of them are common ones; but some—such as trepanation of the nasal cavities and frontal sinuses, and lumbar puncture—are as yet little practised in England. Special attention is given to operations upon the intestines; and one valuable feature is the description, with figures, of a series of intestinal sutures, some of which will be new to many English practitioners. Finally, a short appendix deals with reproduction, parturition, rearing and feeding, and the estimation of age, all of which are treated briefly.

An immense amount of ground is thus covered in a comparatively small space; and it can hardly be said that the results are altogether satisfactory.

Here and there a disease is dealt with fairly fully; and special mention must be made of the long and detailed section, illustrated with eight figures, upon tuberculosis. The authors have had very extensive experience of tuberculosis; and this section alone renders the book valuable to all who are concerned with canine practice. On the other hand, so many important conditions, such as ascites, mammitis, chronic nephritis, and jaundice, are dismissed in little over a page or even less, that we are forced to regard the work as a whole as a little over-condensed.

Still, the condensation has been excellently done; the most essential points are well selected and clearly stated, and if at times the treatment advocated differs from that current in England, the book only becomes more interesting on that account.

On the whole, it may be fully recommended as a succinct *résumé* of clinical canine medicine and surgery. One of its advantages to English readers is that the French in which it is written is comparatively simple.

W. R. C.

ELECTION ADDRESS.

*To the Fellows and Members of the
Royal College of Veterinary Surgeons.*

Gentlemen,

I beg to offer myself as a candidate at the forthcoming election.

I would support rational measures of progress, the maintaining of the present educational standard of the preliminary examination, and any measures which have for their object the obtaining of a fuller recognition in Public Health matters of our profession, and the raising of our status generally.

I am in favour of the Veterinary Surgeons Amendment Bill now before Parliament.

Should I have the honour of being elected you may rely my giving any matter brought before us my most careful consideration, always having in view the advancement of my profession.—I am, gentlemen, your obedient servant,

J. C. COLEMAN.

The Exmoor pony of England, says a New York writer, is classed as the peer of all ponies by many experts. For centuries these ponies have been bred wild on the moors of south-west England. The native stock has been improved by the use of Arabian and thoroughbred blood. Representatives of the breed are of the draught horse type, showing strong, well-knit frames and standing from 13 hands to 14 hands. They are ordinarily bay in colour and are sure-footed, as well as extremely docile. Exmoors are used as harness ponies for light vehicles, for Polo playing and for the use of children.—*L.S.J.*

In a lecture on "The Cost of Living" delivered before the Manchester Statistical Society, Sir Geo. Paish (editor of the *Statist*) declared that from 1896 to 1913 there was an advance in the price of vegetable food of nearly 50 per cent.; from 1896 to 1913 there was a rise of nearly 36 per cent. in the price of animal food, and that from 1898 prices of raw textiles had advanced 64 per cent.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, May 12.

REGULAR FORCES. ARMY VETERINARY CORPS.

Major H. T. Sawyer to be Lieut.-Colonel. Dated April 25.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Capt. E. Franklin to be Major. Dated April 30.

Personal.

Vet.-Capt. ADRIAN JONES has at the Royal Academy exhibition a large portrait of [Field] Marshall Earl Roberts, on his charger (No. 317); also in the sculpture (No. 2041) the late Field Marshall Sir George White, v.c.

Mr. W. F. HOUSTON, M.R.C.V.S., Paisley, was one of the judges of Light-legged horses at the annual show of the Bute Agricultural Society held at Rothesay, on Tuesday, March 5.

Mr. MARSHALL, M.R.C.V.S., Aberdeen, is to be judge of Horse-shoeing at the Central Banffshire Summer Show at Keith in August.

Mr. WILLIAM BRAES, M.R.C.V.S., Linlithgow, is to be one of the judges of Extra horses and ponies at the Annual Show of the Eastern District of Shropshire Association on Saturday, May 30.

GREENING—STANDLAKE.—On the 7th inst., at Clapham, Sydney Herbert Greening, fourth son of the late H. B. Greening, Esq., M.R.C.V.S.L., of Brixton Hill, to Ellen Standlake (*née* Beauchamp).

OBITUARY

GEORGE LEWIS YEATMAN INGRAM, M.R.C.V.S., late of the Brown Institution. Lond: July, 1909.

Death occurred on May 12th, at The Myrtles, Chew Magna, Somerset, at the age of 30.

PERCY BOULTON SPOONER, M.R.C.V.S., Florence Street, Islington. Graduated, Lond: Jan., 1877.

Mr. P. B. Spooner, who died at Islington on Monday 11th inst., was 57 years of age. He was son of the late Prof. Charles Spooner, who joined the staff of the Royal Veterinary College in 1838 and was Principal 1853 to 1872; and who was one of the signatories to the petition for the Charter of 1844; was a member of Council from 1844 to 1871, and President R.C.V.S. 1858-59. Mr. P. B. Spooner had for many years a large horse practice in Islington, much of which remained with to the last.

CRANFORD.—At Bangalore, S. India, on the 4th April, from enteric fever, Ethel Constance, the beloved wife of Major R. L. Cranford, A.V.C.

GAMMELL.—On the 7th May, suddenly, of heart failure, William Gammell, late of Camden Town, in his 75th year.

At a meeting of the directors of the Highland and Agricultural Society held at 3 George IV. Bridge, Edinburgh, a letter was received from Sir Stewart Stockman asking the Society to appoint a delegate to attend the Tenth International Veterinary Congress, which is to be held in London during August. After some discussion it was decided not to send a delegate.

CORRESPONDENCE.

VETERINARY INSPECTION V. THE POLICE.

Sir,

Your editorial in this week's issue of *The Veterinary Record* referring to Mr. Brittlebank's well thought out and excellent address given before the North Midland V.A. strikes an important note.

I strongly agree with you the position of the police as a body in very many instances acts more as a sedative than a stimulant to the smooth working of the various Orders under the Contagious Diseases Animals Acts. No one would advocate the removal of the police *in toto* from the field of action, they have a useful and important work to perform as policemen, and will continue to do so as long as human nature is what it is. Under existing regulations, however, speaking generally, the police inspector is a more important personage than the veterinary inspector, and much as we professional men would like to ignore and contradict this point, there is no denying the truth of this assertion. This state of affairs places veterinary surgeons in most invidious positions, and I know of more than one instance where high class practitioners, men of *locus standi*, have declined to act under existing arrangements. I wonder what some of our *confidres* in the sister profession would say if they were asked in their professional capacity to act subservient to a police inspector, and I should also like to know what punishment the General Medical Council would mete out to a member so degrading himself.

Take the average police inspector serving under the Animal Diseases Act and see what manner of man he is. We find he begins life as an ordinary policeman, and in rural districts passes through the various phases before he blossoms out as a superintendent. This step at once qualifies him to become a fully-fledged police inspector under the Animal Acts. His general knowledge and training is, at the most, what he has picked up in a Board School; his training upon animal diseases and the Acts pertaining thereto is absolutely *nil*. Nevertheless, he is placed in authority, and has the administration of these Acts largely in his own hands.

Given time and experience he will one day become conversant with the proper working of these, but in the meantime he walks on the edge of a precipice and may fall at any moment. All outbreaks of animal (scheduled) diseases occurring within his district are reported to him, he visits them and investigates them, he may even act as his own diagnostician and rely upon his own judgment, or he may enlist the services of the veterinary inspector and give the latter his "marching orders," a somewhat incongruous position for the intellectual and highly trained veterinary surgeon who, before he can enter upon his professional studies at all, must pass a general knowledge examination equal to that of a medical man, serve four years at a veterinary school and pass in deep scientific subjects, before he can receive the "hall mark" to practise his profession. He leaves his College a man of culture and an expert in animal diseases, which ought clearly to entitle him to be the chief moving force where all animal diseases are concerned, and he should look to no one for instructions save to his professional chief.

Moreover, the overlapping of the police inspector upon the professional inspector's duties must in many instances lead to friction, and especially where the administrative ignorance of the former is so patent. Let me illustrate a point of fact. A police officer was raised to the rank of a superintendent, and as such became a police inspector under the Contagious Diseases (Animals) Acts. The veterinary inspector was instructed to investigate an outbreak of anthrax, and only reported it as such. A few days later a farmer in the same district called upon the veterinary inspector and complained to him upon the removal of the remaining cattle from the infected field along the highway which, in so doing, passed complainant's cattle, and adding at the same time if any of his cattle died from anthrax he would hold the veterinary inspector responsible. The

veterinary surgeon assured him he had given no authority to have the cattle removed along the highway. On enquiry later this authority was given by the newly appointed police inspector.

The veterinary inspector from a strict sense of duty reported this irregularity to the authorities, and of course in so doing made a mortal enemy of the police inspector.

Had this veterinary surgeon been out for personal gain only, he would have argued "what difference does it make to him how cattle are moved about," nay, more, he might have added such procedure would bring more grist to the (his) mill, and been content to let it remain there. Not so, he preferred, at the risk of even losing his inspectorship, to prevent a repetition of such conduct. And this is the sequel which follows. From that date onward requests made by the police inspector to investigate outbreaks arrived at most inopportune moments of the day, although the veterinary inspector had regular consulting hours, and in some instances delay in investigations were entailed.

These cases were strung together and extended over a considerable period and laid before the local authority who gave the police inspector the option to choose an additional veterinary surgeon. This veterinary surgeon I believe, has been removed from the Register of the College for a grave offence he committed under the Contagious Diseases (Animals) Acts.

This case only goes to illustrate the power a police inspector has if he chooses to exercise it, and the helplessness of the position of the veterinary inspector in his endeavours to carry out his duties in a conscientious and manly spirit.—Yours truly,

PRACTITIONER.

TREATMENT FOR SCLEROSTOMUM ARMATUM.

Sir,

I have a three-year-old hunter bred gelding which has done very badly the last six months owing to suffering from worms (*Sclerostomum armatum*). He has not grown at all, looks a bag of bones in spite of getting a lot of food, is pot-bellied, and has a staring coat, etc., etc. I have given him worm and tonic powders and also *Liq. arsenicalis*, but no medicine seems to do him any good.

Other veterinary surgeons have told me that they have had similar cases, but that usually the owners have sold the colts after having suffered from this disease for some months.

I would be very much obliged if your readers would give me their experience, especially as regards whether any of their patients suffering from this disease have made a complete recovery.

Perhaps a summer's run at grass may have a beneficial result.—Yours truly,

GRAHAM REES-MOGG.

May 12.

NATIONAL V.M.A.—A correction.

In the report of Council meeting last week, p. 721, the paragraph at the foot of first column should follow the next paragraph, after the word Edinburgh.

NORTH MIDLAND V.M.A.

Sir,

In the report of the meeting of the North Midland V.A. I am reported as advocating the sending of bovines suffering from tuberculosis with emaciation to the knacker's without inspection of other animals on the farm or premises. I think my further remarks will show the necessity of such inspection.—Yours truly,

J. POLLARD.

Halifax. May 12.

VOL. XXVI.

THE MILK AND DAIRIES BILL.

The New Milk and Dairies Bill is now before Parliament and perhaps has a better chance of becoming law than its predecessors. Its present inceptive stage, at which it is still capable of modification, is the best time to consider such of its provisions as affect us. One fact, which some members seem sometimes to forget, should be kept in mind throughout—that there is a great deal in any Milk Bill which has very little to do with our profession. But, so far as this one does concern us, it may at once be said that it is a great advance upon the preceding Bills.

It will be remembered that the Bills of 1912 and 1913 empowered the M.O.H. to inspect cattle "if accompanied by a veterinary inspector or some other properly qualified veterinary surgeon." Veterinary opinion was unanimous in disapproving this proposal; and the present Bill meets our objections. Section 12, Subsection 4 says definitely "Any inspection of cattle made in pursuance of this Act or any Milk and Dairies Order shall be carried out by a veterinary inspector or other properly qualified veterinary surgeon." This puts the M.O.H. and the veterinarian in their proper positions at once—the former has power to cause cattle to be inspected, but the latter alone can inspect them. Further, in the section of interpretations, we read that "The expression 'veterinary inspector' means an inspector being a member of the Royal College of Veterinary Surgeons, or having such other qualifications as may be approved by the Board of Agriculture and Fisheries." So long as the Board of Agriculture alone can authorise the substitution of other qualifications for the M.R.C.V.S., we are content. To obstruct a veterinary surgeon in exercising his powers under the Act or its Orders, again, is as penal as to obstruct the M.O.H.

In other respects the Bill is a very wide one. It empowers the Local Government Board to issue General Milk and Dairies Orders; but only with the concurrence of the Board of Agriculture—a valuable provision—and the consent of both Houses of Parliament. Thus it will be possible to considerably extend the effect of the Bill by subsequent Orders. At present the measure only applies to milk of cows which have given tuberculous milk, or which are suffering from any of the forms of tuberculosis dealt with by the Tuberculosis Order, "or from acute inflammation of the udder, or from any disease liable to infect or contaminate the milk." Many other questions, such as registration of dairies, and the colouring, adulteration, cooling and conveyance of milk, are left to be dealt with by Orders.

The penalties the Bill imposes are not heavy for first offences, but may be made so for old offenders or for "continuing offences." A prosecuting authority may take proceedings against any person believed to be the actual offender against the Act, without first proceeding against the occupier of the dairy concerned.

Further, a dairyman summoned for an offence under the Act may simultaneously summon another person charged by himself as the actual offender, and may thus exempt himself. There is much to be said for both these provisions; though the last one may lead to a good deal of hard swearing.

Local authorities may appoint veterinary inspectors and arrange for bacteriological examinations of milk of their own accord, or may be obliged to do so by the Local Government Board. When a M.O.H. finds that tuberculous milk is coming into his district from that of a second M.O.H., he must report to the latter, who must then cause all necessary inspection and investigation to be made, and allow the first M.O.H. or his veterinary surgeon to be present at such inspection if desired. Copies of all official reports, and information as to any action which may have been taken upon them, must then be supplied to the first M.O.H. This seems a sensible way of dealing with cases that often cause difficulty.

It is quite obvious that the working of this Bill will overlap not a little with that of the Tuberculosis Order. The main purpose of the Bill is to prevent the sale of tuberculous milk; the sole purpose of the Order is to detect and destroy tuberculous cattle in certain stages of the disease. Very often inspections under the Bill will result in the discovery of cows that require to be dealt with by the Order; and a dairyman may be found liable to prosecution under either measure. But often—perhaps generally—the veterinary inspection under both Milk Act and Tuberculosis Order will be done by the same man, and this will tend to simplify matters. Further, one lengthy subsection in the Bill enables the Local Government Board to determine by Order which of its powers are to be exercised by sanitary authorities and which by County Councils, to relegate any such powers to the local authorities for the purpose of the Diseases of Animals Acts, 1894 to 1911, and to provide for all necessary intercommunication between any of these different bodies. If this clause becomes part of the Act, it may do much to facilitate its working.

From our point of view, the most valuable features of this Bill are the full recognition it gives to the veterinary surgeon, and the fact that it allows the Board of Agriculture some control with the Local Government Board.

X-RAYS IN CANINE PRACTICE.

The enclosed two photos of the abdomen of a fox-terrier, taken by an X-ray expert, to locate a bullet, may be of interest to your readers. They show very distinctly the bullet in the abdomen.

I was called to see the dog on Saturday evening and found it with a small wound on the right flank in line with the point of the ilium. The dog was fairly brisk but lay all the time, and when forced to move walked along on his fore legs, never putting the hind ones to the ground. The owner wished everything done for him, and I suggested having the X-rays taken to ensure location of the bullet. This was done on Sunday morning. The owner asked for an operation on the dog, but when the abdomen was opened peritonitis had set in, due to the laceration of the cæcum, and so chloroform finished the operation.

The surgeon who took the photo suggested leaving the dog severely alone, as he had seen cases of bullets being in the abdomen and never causing any serious symptoms, but I am certain that if this dog had been left alone he would have died in a very short time.

JOHN TAYLOR, M.R.C.V.S.

Edinburgh. May 12.

ABSTRACTS FROM FOREIGN JOURNALS.

THE EFFECT OF AGITATION OF CULTURE MEDIA UPON THE GROWTH OF BACILLI.

A. Lucet, in 1911, showed that a gentle and continuous movement of bouillon tubes in which anthrax bacilli are being incubated furnishes more abundant bacterial growths than those obtained by the usual methods of cultivation. The same author now publishes (*Recueil Vétérinaire*) the results of further experiments, which entirely confirm and extend his previous conclusions.

The bacterial yield of cultures in liquid media is considerably augmented by subjecting them to a gentle agitation, and this is true of other germs in addition to those of anthrax. The same rule applies to the microbes of cholera, typhoid fever, diphtheria, blue pus, glanders, dysentery, streptobacillosis of the rabbit, erysipelas, and even to the anaerobic organisms of tetanus and black-quarter. The microbes cultivated in this manner present important modifications in their form. They are shorter than those grown by the usual method, they stain less intensely, and they are poor in spores. The culture medium, also, appears more viscous and more deeply coloured in this method of cultivation. The virulence of the bacilli does not appear to be lessened.

The author attributes this increased microbial proliferation to two causes. In the first place the agitation establishes a better contact between the bacilli and the nutritive medium. Secondly, the agitation disperses the toxic products which the

bacilli secrete, and which, in a still medium, accumulate in their neighbourhood and destroy the powers of assimilation.—*Annales de Méd. Vét.*

THE ÆTIOLOGY OF ACNE.

Ludwig Rimpl has been working upon acne in horses and dogs, and endeavouring to demonstrate the specific cause of the disease by cultural and inoculation experiments. Altogether he has worked upon twenty cases of acne (thirteen horses and seven dogs). He publishes (*Oesterreich Woch. f. Tierheilk*) his conclusions, which he summarises as follows:—

1. Acne in domestic animals is caused by staphylococci. The most important of these is the *Staph. pyogenes aureus*, the second in importance is the *Staph. pyogenes albus*, while the *Staph. pyogenes citreus* seldom causes acne.

2. From a morphological, biological, and pathogenic point of view there is no distinction between staphylococci from a case of acne and pathogenic staphylococci of other origin.

3. Friction, sweat, and the other factors which used to be quoted as causes of acne have only a predisposing influence.

4. Acne cannot be produced with the streptococci of strangles.—(*Berliner Tier. Woch.*)

HÆMOGLOBINURIA IN FOALS.

Kränzle, of Griesbach, briefly describes a peculiar disease which he has repeatedly observed during recent years, and in the present year also. In most cases it attacks young horses, and more especially yearling foals. It begins with a severe inflammatory unilateral or bilateral swelling of the muscles concerned in mastication. The masseters feel as hard as boards, and the animals can only open their mouths with difficulty and cannot take food. In most cases the swelling of the muscles soon disappears, but a paralysis of the same muscles remains, so that, though the animals generally show appetite, they starve through inability to take food.

Very often, but not always, hæmoglobinuria appears late in the illness. In many cases it exists from the beginning, so that the disease can be diagnosed as "hæmoglobinuria," with the distinction that the masticatory muscles are affected, and not those of the croup. Despite all possible endeavours Kränzle has not yet succeeded in saving a single animal affected with these symptoms.—*Munchener Tier. Woch.*

[Nothing is said of post-mortem examinations.—*Transl.*]

Last year the receipts at the Metropolitan Cattle Market at Islington amounted to £26,462, as compared with £24,805 the year before. The supplies of animals numbered 315,206, as against 308,193 in 1912 and 404,883 in 1911.

The number of home animals sent for sale continues to decrease, but the number of beasts consigned direct to the public slaughterhouses shows a large increase, due primarily to the absence of foreign cattle.

Royal College of Veterinary Surgeons.

FELLOWSHIP DEGREE.

A meeting of the Board of Examiners for the Fellowship Degree was held at the College, 10 Red Lion Square, W.C., on Saturday, May 16th, 1914. The following is a list of the successful candidates, together with the titles of their respective theses:—

BAGENAL HARVEY MELLON, "An account of some aspects of disease as it affects the brain of the horse."

JOHN HOLROYD, "Embryotomy."

The Examiners were Prof. J. Macqueen, Messrs. J. Malcolm and W. Woods. Mr. W. J. Mulvey in the chair.

FRED BULLOCK, Secretary.

NATIONAL VETERINARY MEDICAL ASSOCIATION

INSURANCE FEES.

The final meeting of the Special Committee appointed to deal with this matter, met on Wednesday, the 13th inst., at Tonbridge.

The question of mileage was again fully considered, and it was unanimously resolved to put this in the form of an additional fee, as shown on the accompanying scale, which was adopted by the Council of the Association at their meeting on the 14th of March last, for reasons stated in the circular letter.

The Secretary was directed to send copies of the prepared scale to all affiliated Societies in the kingdom forthwith, asking for their support and its adoption by them.

Scale of Fees as finally adopted by the Council of the National Veterinary Medical Association at their sitting on 12th March, 1914, for examination and report on general health, condition, age, colour, markings, and approximate value of animals, proposed for insurance:—

HORSES AND VALUABLE PEDIGREE CATTLE.

- | | |
|---|------|
| (a) Single animal under the value of £50 | 5/- |
| Two animals " " " Each | 5/- |
| After the first two | 2/6 |
| (b) Single animal valued at £50, under £100 | 10/6 |
| (c) Single animal " £100, " £250 | 15/- |
| (d) Single animal " £250, " £1000 | 21/- |

If more than two animals are examined, the third and all subsequent ones at half the above charges.

STORE CATTLE, ORDINARY MILKING COWS, ETC.

- | | |
|---|------|
| (e) Single animal | 5/- |
| Two or more animals per head | 2/6 |
| (f) Special reports on illness, accident, etc. | 10/6 |
| (g) Post-mortem examinations and reports each | 21/- |
| (h) Other stock, sheep, pigs, etc., in considerable numbers, by special arrangements. | |

The above fees are for services rendered at the Veterinary Surgeon's establishment, or within the distance of one mile thereof. For allowances beyond one mile the following additional fees are to be charged in lieu of mileage:—

From 1 to 3 miles, 1/-; 3 to 5 miles, 2/6; 5 to 8 miles, 3/6; beyond 8 miles in proportion.

THEO. C. TOOPE, Hon. Sec. Southern Branch.

NATIONAL VETERINARY MEDICAL ASSOCIATION. 34 High Street, Dover.

Dear Sir,

May 18, 1914.

I am directed by the Council of the Association to send you a copy of the enclosed scale of fees for services rendered to insurance companies by veterinary surgeons in the hope that your members will likewise adopt them, and induce other veterinary surgeons to do so. They have been most carefully considered and have been agreed to practically with unanimity by the Special Committee appointed, and also by the N.V.A. Council.

I shall be glad if you will bring the matter before your members at their next meeting, and on hearing from you as to your requirements I will forward the necessary number of copies to circulate in your district.

I may add, that my Divisional Society, the South Eastern, at their last meeting, have already unanimously adopted them as the lowest terms under which our members will render service in the future.

It has been deemed advisable to put the mileage in the form of an additional fee, otherwise it was thought possible that local authorities might possibly copy the reduced scale as first suggested to our detriment, in many districts, as veterinary inspectors.

Unity is strength, let us again show the force of this axiom.—Yours very faithfully,

THEO. C. TOOPE, Hon. Sec. Southern Branch.

CENTRAL VETERINARY SOCIETY

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The usual monthly meeting was held at 10 Red Lion Square, W.C., on Thursday, May 7th, Professor G. H. Wooldridge, President, in the chair. The following Fellows signed the attendance book: Messrs. B. Gorton, W. N. Thompson, F. G. Samson, R. J. Foreman, J. F. Macdonald, L. Auchterlonie, J. W. McIntosh, G. H. Livesey, Prof. E. B. Reynolds, R. Eaglesham, J. Willett, J. B. Buxton, F. W. Willett, C. Cunningham, R. Bryden, N. Almond, C. H. Sheather, R. W. Clarke, G. Gordon, A. E. Bayley, B. A. McGuire, Prof. J. Macqueen, and Hugh A. MacCormack, hon. sec. Visitor: H. H. Curson.

On the motion of Mr. McIntosh, seconded by Mr. Samson, the minutes of the last meeting having been published were taken as read. As they were not yet all affixed in the minute book, the signing was deferred to the next meeting.

Correspondence. The SECRETARY stated that he had received a letter from Sir Stewart Stockman, respecting the International Veterinary Congress, and another from Mr. Joseph H. Carter (President of the R.C.V.S.), relating to the pension for the dependents of the late Mr. Hunting.

On the motion of Mr. McIntosh, seconded by Mr. J. Willett, the President was asked to attend the Congress on behalf of the Society. Prof. Wooldridge assented.

On the motion of Mr. Foreman, seconded by Mr. Livesey, the meeting endorsed the action of the President in signing the "Hunting" petition on behalf of the Society.

MORBID SPECIMENS.

The PRESIDENT referred to the specimen, submitted by Mr. Livesey at the last meeting, of the penis of a dog in which hæmorrhage had been taking place for a considerable period. The speaker had been requested to have sections cut and examined, as Mr. Livesey thought that there might be some malignant growth. On cutting the sections and examining same, however, he had

found no signs of such growth, the thickening observed being connected with the scar tissue. A puncture led into some of the caverns or sinuses of the *corpus cavernosus*, suggesting that the original injury was some wound in one of the sinuses, and that, owing to intermittent erections and hæmorrhages, healing had been retarded. There was no injury to bone, so far as he could see. It was difficult to explain the fact, pointed out by Mr. Livesey, that there were sometimes intervals of six or eight weeks between the hæmorrhages; microscopic examination revealed no cause for the peculiarity beyond the presence of the wound.

DILATED ŒSOPHAGUS IN THE REGION OF THE NECK IN HORSES.

MR. N. ALMOND introduced to the notice of Fellows two cases which had come under his observation, and which, so far as he knew, were unique. He was therefore desirous of obtaining opinions as to the frequency of such occurrences. Fellows would be more or less aware of the acute diseases of the œsophagus, and the trouble and fatality attending them; but the cases to which he was referring were not of that character. These cases consisted in the existence of a kind of pouch at the lower third of the cervical portion of the œsophagus, and during the period of feeding, as well as for some time after, these pouches were, to a greater or less extent, distended with ingesta.

The first case was one of an ordinary van horse, which did all kinds of work of a market gardener for thirteen years. The horse was in the habit of travelling from a place beyond Hampton to London three times a week. Sometimes the œsophagus would be distended by ingesta to a greater extent than usual, and, in these instances, the carter who had charge of the animal was accustomed to manipulate the part, and in that way successfully endeavoured to pass the food on.

The second case was under the speaker's notice at the present time. It was a seven-year-old gelding, bought as a good worker, at an auction, for £20. At the time of the auction the purchaser did not observe any defect, but soon after the animal was taken home he noticed a swelling in the neck. Being alarmed, he had consulted the speaker, who, but for his experience of the first case, would have shared the alarm. For six months the horse had been doing work incidental to the business of a furniture remover. The animal was a roarer, and would make a noise when going up a long hill, but showed no distress when ascending a short hill. It made rather more noise after feeding, and the practice had been adopted of feeding it earlier than the other horses, so as to afford opportunity for any difficulty to be got rid of before the animal started. The horse apparently suffered no inconvenience, and the owner had consulted Mr. Almond as to whether he should keep it or sell it. Having the first case in mind, and the horse being a good worker, such as would ordinarily cost £35 to £40, the speaker advised his client to keep the horse notwithstanding that it was a roarer. He might say the animal had worked well ever since. Water was given after feeding in order to rinse out the gullet. The first drink generally caused a cough, and when the animal drank a second time there was usually no further cough. The water distended the gullet to some extent, and there might be a little food remaining, but this was easily passed on by manipulation. On one day the horse had done 45 miles between 6 a.m. and 10 p.m. without harm resulting, and on the next it did its ordinary local work. He thought the case an interesting one, and he desired to have the opinion of Fellows as to the prospect of life, and as to the representations to be made to the insurance company in case it were desired to effect an insurance.

MR. FOREMAN observed that the cases just submitted brought to his mind a cases which happened about

fifteen years ago, and which he regarded as similar. He had endeavoured to pass the probang in the upstanding position, but it would not pass a swelling in the neck. He then cast the horse, and although using considerable force, failed to pass the probang. When the animal rose he told the man in charge to rub in stimulating liniment. He also gave the animal a hypodermic injection of morphia. The trouble then passed away, recurred several times, but did not require active treatment. As he had been unable to remove the obstruction he supposed the probang had got into the sac.

He had knowledge also of a similar case in a human being, but in this instance the person was able to regurgitate the food when it got into the sac.

On the question of insurance, he should describe the horse to which Mr. Almond referred as a "bad life."

MR. SHEATHIER enquired whether, in the first case mentioned by Mr. Almond, the malady was of gradual growth, or had existed for the thirteen years referred to. To this Mr. Almond replied that the trouble was regular with the horse, and had existed, at all events, for several years.

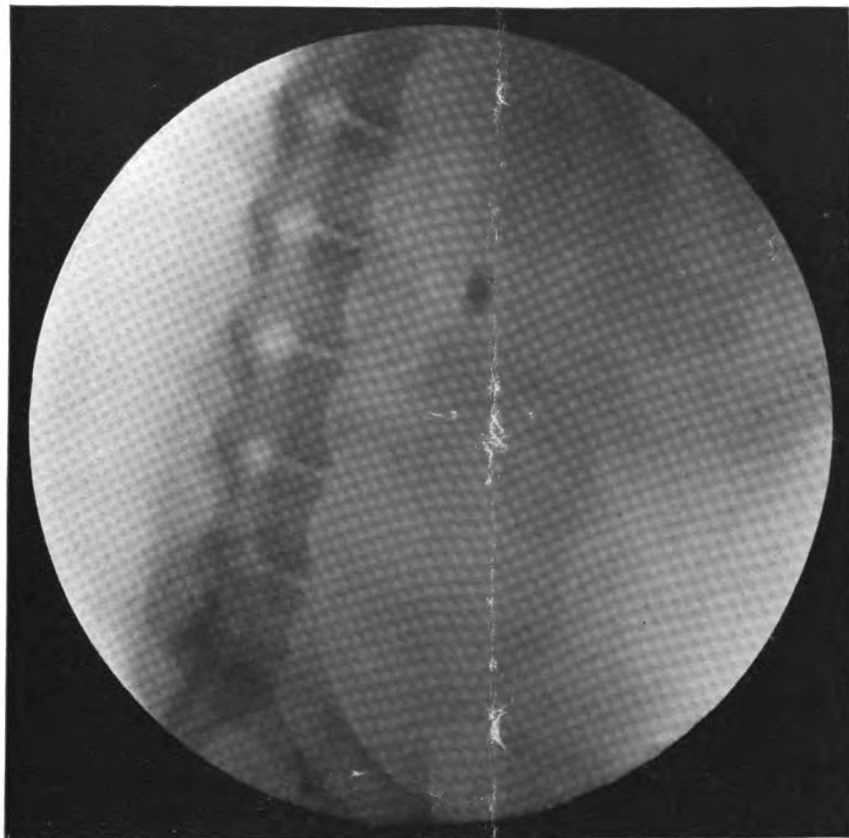

Mr. Sheather, continuing, stated that he had experience of one case. His father having been called to see a thoroughbred mare which had a wound on the neck through which was discharging food. His father had cast the mare, giving her chloroform, and endeavoured to find out at what point the œsophagus was perforated. With the object of trying to suture the œsophagical wound, he had made an incision over the swelling. He then found that the membranous lining of the œsophagus was burst and was in small shreds. Nothing could be done, and the mare was destroyed.

MR. WILLETT enquired of Mr. Almond whether dilatation took place after every meal, or at intervals of two or three days. He was informed that it happened whenever the animal fed.

MR. COLEMAN referred to a case of which he believed he had already submitted details to the Society. A polo pony had shown swelling in the region of the lower third of the cervical portion of the œsophagus immediately upon drinking a quantity of water. This would disappear again in a short time and seemed to cause the animal little or no inconvenience. The animal had come into his hands after being affected in this manner for three years, and he had destroyed it. He found upon post-mortem examination an egg, which was covered with inflammatory tissue to the thickness of about half-an-inch attached to inner wall of œsophagus in the thoracic portion just before passing through the diaphragm.

Another case was that of a three-year-old entire horse. It had had strangles some ten months ago, and had presented a swelling in the lower third of the œsophagus at intervals for the past eight months outside the thorax, and only on one side. He had not then diagnosed the case as one of dilatation of the œsophagus, although strongly suspecting this condition. He had instructed the owner to take the horse in and keep it without food or water for two days. The horse apparently recovered, the swelling disappearing, and the speaker was told not to trouble further. He had, however, been interviewed on the previous day, and had been informed that the swelling had reappeared. His intention now was to castrate the animal, to keep him quiet, and apply a blister over the region of the swelling; the animal was to be kept on emulsient food for a fortnight or so afterwards. The animal showed no signs whatever of distress.

The PRESIDENT had seen only two cases in which the condition corresponded with that described by Mr. Almond, and in each case food was returning through the nostril, particularly the water. If the horse were kept without food and water the swelling subsided. Then, when a pail of water was given, by placing the

BULLET IN THE ABDOMEN OF A FOX TERRIER.

Illustrating note by Mr. J. TAYLOR, M.R.C.V.S.

hand over the place where the dilatation had previously occurred, the water could be felt rushing into it, and a little must evidently have passed through, because the swelling did not increase in the same degree as the water disappeared from the pail. By leaving the animal alone, so far as administration of remedies was concerned, he seemed to recover himself. If the dilatation contained solid food the horse was given a pail of water and the swelling was manipulated to allow the water to get into the part, soften it, and gradually pass through. The horse was not at all distressed. Subsequently the animal was lost sight of. The foregoing remarks applied almost identically to the second case which came under his notice.

As to the prospect of life, he agreed with Mr. Foreman, and in spite of the fact that the horse mentioned by Mr. Almond had gone on fairly well for thirteen years, he would not pass such a horse for insurance. There were cases of men who had, in their early days, been refused by insurance companies but had yet lived to ripe old age; he believed such cases, however, to be quite exceptional. He would ask Mr. Coleman whether he thought castration in his case would have any sort of influence on dilatation of the œsophagus.

Mr. Coleman replied that his object had merely been to keep the animal quiet.

Mr. ALMOND enquired whether the return of food or water through the nostril was invariable.

Prof. Wooldridge replied that during the week he had the horse under observation, water and small amounts of food were returned after drinking.

He considered that cases of reported vomiting in the horse were due to a similar condition intra-thoracically. He had not been able to make any post-mortems in such cases, but he suspected such a condition.

Prof. REYNOLDS asked for more details of the condition observed in the horses. Mr. Almond had stated that the trouble occurred every time the horse was fed, and the speaker would enquire whether the animal ate all the food provided at one time. He could not understand why water was given when the œsophagus was dilated with food. He would have thought it was a serious matter to give the horse water, but since this was done he would ask if the animal was able to swallow water, and if so, in what quantity, and whether easily? Did the swelling go down after the water had been taken? If the swelling remained, and the animal could swallow water, that would appear to indicate that it was a pouch on the side of the œsophagus that was filled with food, and not a dilatation of the whole œsophagus. After food did any acute symptoms of choking occur, such as retching or salivation? He would describe a horse in the condition named by Mr. Almond as unfit for insurance.

Prof. MACQUEEN desired to ask Mr. Almond whether he had ascertained if the dilatation referred to was a simple dilatation of the gullet or a dilatation associated with rupture of the muscular coat. The former was not uncommon, while the latter was. The position of the dilatation was not always at the root of the horse's neck, but was sometimes within the thorax, close to the diaphragm. With regard to cause, he thought dilatation in the inferior region of the neck was usually preceded by choking, and, either in the efforts made by the horse to relieve itself from the obstruction or the efforts of the veterinary surgeon to effect relief, the mucous membrane became injured. In course of time this would be followed by stricture. Whenever there was stricture, dilatation would take place, immediately above the constricted portion. There was a possibility, of course, that dilatation of the gullet did occur as a primary condition where an animal had swallowed some foreign body, which became arrested for a time in the gullet as it entered the thorax; but in most cases dilatation followed stricture. At the region mentioned by

Mr. Almond the œsophagus made a curve in entering the thorax, and was particularly exposed to injury from the passage of the probang, especially when the latter was passed in the standing position.

The interesting point as to the prognosis turned on the condition of the gullet as a whole. If the dilatation consisted of dilatation of the mucous membrane and of the muscle, it was very likely that the dilatation was gradually produced, and the condition was akin to the crop of a bird; the animal might continue to be serviceable for many years, though he would probably require to be fed with considerable care. If, on the other hand, dilatation was due to rupture of the muscular coat, there was, of course, great danger of perforation of the mucous membrane. Then, perhaps, attention was directed to the case by the formation of a swelling without any known history of an injury. An abscess formed and there was a discharge; on exploration the discovery was made that the abscess was in communication with the gullet. In thoracic cases there was nearly always regurgitation in the intervals between feeding; very frequently the animal salivated and the appetite might be very defective. But, in these cases, he was unaware of any useful treatment. They generally led to the death or involved the destruction of the horse, according to the speaker's experience. He would personally have advised the destruction of the animal referred to by Mr. Almond as a roarer if the roaring was caused by pressure of the dilated gullet.

Mr. ALMOND, replying to the discussion, pointed out that he had not connected the roaring of the horse with the dilatation of the œsophagus; the two pathological conditions might co-exist without relationship. While thanking Fellows for their comments, he could not trace much connection between the cases he had brought forward and those submitted in the course of the discussion, inasmuch as the latter were more or less all acute cases. The case mentioned by Mr. Foreman, for instance, was one of choking—obstruction in the œsophagus, which differed entirely from the cases submitted by the speaker, where there were no acute symptoms. In these latter cases the horses did their ordinary work, and in the first case the animal was treated as an ordinary horse, going a distance of twelve miles or so to London and back three times a week, and doing home local work on other days. In the second case also the horse was doing ordinary work in furniture removing. The work (of which he had given particulars) was done without distress, and there were no acute symptoms. He had himself formed the view taken by Prof. Macqueen, that the condition was an abnormal one and resembled the crop of a bird; of course he was not aware that any digestive work was going on there.

Turning to Mr. Sheather's case of rupture, there again there was an absence of any resemblance. The case mentioned by Mr. Coleman was somewhat similar to that to which he had directed attention, inasmuch as there did not seem to be any acute symptoms, and the animal was not distressed. In such a case, judging by his own experience, there seemed to be no reason for treatment; indeed, he thought treatment was more likely to do harm than to do good. He was basing his opinions upon the only two cases of which he had knowledge. Prof. Wooldridge had referred to a case, common enough, of an acute nature—obstruction in the œsophagus.

Prof. WOOLDRIDGE desired to point out that the cases he had referred to were of marked dilatation of the œsophagus and not of marked obstruction. When the animal took food or water it remained for some time in the dilated portion of the gullet. He failed to see that water in that place could be a cause of obstruction. There may have been a cause of obstruction posterior to that, and this he assumed to be a stricture. He had not dwelt further upon the point, and stated

what he thought to be the cause of the dilatation of the œsophagus, but had assumed that the swelling of the œsophagus was due to some posterior trouble. Cases of œsophageal choking in the horse, especially in greedy feeders, were not at all rare, and the speaker would certainly not have stated that he had met with only two cases of obstruction in the œsophagus.

Mr. ALMOND, continuing, said that in answer to Prof. Reynolds he would state that there was no evidence that the whole of the œsophagus was dilated. The swelling occurred in the lower third of the cervical region, what might be beyond or posterior to that he could not say. The principal fact was that the animals were in no way distressed. In common with other practitioners, he had experience of several cases of disease of the œsophagus leading to a fatal issue, the causes of which were well known; he had made post-mortems which revealed the causes clearly. As he had said, after feeding a certain amount of food was left in the lower part of the œsophagus, which, on discovery, owners endeavoured to remove by manipulation. The amount resting in the œsophagus was not always the same, it depended to some extent upon how long before the animal had been feeding. If there were much distention it was customary to manipulate the part and give the horse a drink of water. With the first drink came the cough, the swelling passed away, and the horse drank ordinarily. In the particular case to which he was referring it was the practice to give the horse water after feeding. He had mentioned the fact that the horse was a roarer, because the horse was bought for £20, but was doing the work of a horse that would cost £60 or more.

He might have been misunderstood, but there was no reason why he should associate roaring with dilated œsophagus. He saw no reason either for destroying the horse, as had been suggested. Prof. Macqueen had asked him whether he had been able to ascertain if the dilatation included both mucous membrane and muscle. He believed it did. Had there been any rupture of the mucous membrane, he could not believe that the horse would have gone on for so long without showing distress. His impression was that there was no rupture of muscle either; he could not feel any. There was a general rotundity in the neighbourhood and a slight thickening of the part. On manipulating the empty œsophagus, it gave an impression of being somewhat thicker than normal. Neither during dilatation nor when at rest was there any evidence of rupture, so far as the speaker's manipulatory powers conveyed to him.

SOME INTERESTING CASES.

By R. EAGLESHAM, M.R.C.V.S.

SUBCUTANEOUS SARCOMATA IN THE HORSE.

A twelve-year-old black cut gelding, last September showed growths in the subcutaneous tissues which have gradually grown since. These growths are most numerous on neck, about shoulders, and on sides over the ribs, as well as on hindquarters. The largest are about the size of a pigeon's egg, and although not attached to the skin they show up prominently beneath it, especially the largest and oldest tumours.

The horse is in good health, and beyond the appearance of the growths, which are quite free from pain, they do not at present render it unfit for work. The tumours will of course in time get larger. Four of the largest tumours I have cut out, and you will see that they are built up of that embryonic connective tissue which characterises the sarcoma. Two of the tumours I submitted to Sir John M'Fadyean for examination; he informed me that histologically they are of the same

character as the sarcomata. He said the largest size they attain is about that of a goose's egg, and that they never affected the internal organs.

Similar tumours were described by Mr. Park, of the New Zealand Department of Agriculture in 1897 as being due to lymphadenoma and by Mr. Gilruth of the same department later as malignant sarcoma. Mr. Gilruth shows a very good photograph of a New Zealand pony affected with them in *The Veterinary Record* of 24th Nov., 1900.

I should be glad to hear if any of the Fellows of the Society have met with similar cases. It is difficult for the veterinarian to follow these cases to their termination, the animals get worn out and change hands, and thus to get post-mortem examinations is difficult.

RHEUMATIC TENDONITIS.

Rheumatism is a constitutional disease in which fibrous structures, especially joints, muscles, ligaments, tendons, tendon sheaths, and periosteum are inflamed and painful.

It is not now exclusively looked upon as being caused by colds, but due to infectious origin (coccus). Horses may be subject to acute attacks of rheumatism with fever and sudden lameness, with or without swelling of some particular articulation, tendon, or bursa, and the lameness may disappear from one part of the body and reappear in another, as from a foreleg to a hind leg. With a course of treatment internally and locally recovery may be rapid in some of those cases.

The chronic form of rheumatism that I wish to refer to is that which we meet with in the horse following influenza, pleurisy, dropsy or purpura, and is due to infectious origin; it affects the flexor tendons and their sheaths of both front and hind limbs.

Mild attacks following illness may only affect the sesamoidean bursa of one or of all four legs, which may be swollen and painful, and this, with local and internal treatment may pass off without leaving any permanent bad effects.

In the chronic form the disease generally starts in the sheaths of the tendons, and I have found that this form of tendonitis is more obstinate to cure than an inflammation mechanically produced in an animal that is otherwise sound.

Two clinical cases of this class that I have had recently under treatment I wish to bring to your notice—a six-year-old brown cart gelding and a six-year-old bay cart mare. Both these animals had been ill with influenza during the winter of 1912-13, and both had apparently recovered and, on resuming work, both developed lameness, which followed a chronic course in much the same way in both cases, affecting both front legs. The lameness was not very well marked at first in either case; stiffness at first, with a tendency to lie longer in the stall than usual, and on rising cramp of the legs would be shown, which would pass off with exercise. This went on for several weeks before both animals were incapacitated for work through severe and gradually increasing lameness. In the case of the gelding there was no enlargement of the check ligaments or swelling of the sesamoidean bursa, the disease apparently being in the sheaths of the tendons; but in the mare the check ligaments and fetlocks were enlarged.

As time went on the legs assumed an upright or straightened form; and with gradual contraction of the tendons knuckling over of the fetlocks took place. In the end both animals were practically walking on their fetlock joints.

The treatment followed out in both cases in the early stages was both internal and local. Salicylic acid was given internally, and local treatment, bandaging, embrocations, blister, followed by a run at grass; but these

were of no avail, and both cases being incurable the animals were destroyed.

Post-mortem appearances. Thickened check ligaments in the case of the mare, and inflammation of the sheaths of the tendons in both cases.

RENAL DISEASE (CALCULUS) IN A MARE.

The following is an interesting case of chronic nephritis with formation of calculi which I have recently met with in a twelve-year-old bay van mare.

For a period of about two years the mare passed blood casts in the urine intermittently. Beyond this she did not seem to suffer any inconvenience, showing no systemic disturbance, keeping up her condition, and she was able to continue at work. During the last six months she showed impaired appetite, and began to lose flesh, and had to be stopped working. No alteration in pulse or temperature was shown, but symptoms of thirst, weariness, irritation of bladder, manifested by frequent staling of large quantities of somewhat clear coloured urine which smelt badly, were shown. No blood casts were passed in the urine during the later stages of illness. There were no dropsical swellings visible about body or legs; no pain was shown on pressure over loins; and the animal's gait was in no way affected. No colicky pains were shown, nor difficulty in urinating. Rectal examination revealed nothing abnormal with the bladder or ureters.

In the early stages of the disease the urine, tested by nitric acid, showed the presence of albumin. The case was diagnosed as one of chronic nephritis with cystitis, and being considered incurable the animal was destroyed.

The duration of the case from the time blood casts were first noticed till mare was destroyed was 2½ years. The time mare was incapacitated from work about 5 months.

Post-mortem appearances. There were serous effusions around the kidneys. The surface of the left kidney uneven, wrinkled, and felt lumpy and somewhat hard. The pelvis of the left kidney was enlarged, the mucous lining being thickened. The pelves of both kidneys were filled with sabulous matter.

There was formation of small calculi in the structure of the left gland, and the formation of new interstitial connective tissue, causing hardening with a tendency to shrivelling of the right gland. The ureters were thickened and dilated. The bladder: the mucous membrane was inflamed and thickened in places.

All the other internal organs were found healthy.

Remarks. The case seems to me to have been one of chronic nephritis and pyelitis with the deposit of calculi. The presence of gravel and sand in the pelves of kidneys is said to cause pyelitis as well as the presence of worms and calculi.

Pyelo-nephritis is said to be more common in the mare than in the horse from bacillary infection from uterus. The irritation of the ureters and bladder in this case I should say was due to the passage of sabulous matter from the pelves of the kidneys.

DISCUSSION.

Mr. THOMPSON, referring especially to subcutaneous sarcomata, stated that some years ago his attention had been directed to a bay mare which had developed what appeared to be fibrous growths just under the skin on the side of the shoulder and behind the thighs, immediately below where the breeching came. He had had the mare under observation for six or seven years, and the growths increased in size and number until she was a mass of nodular growths under the skin. After a while she became unsightly in the street, and she began to lose flesh. She was sent to the Veterinary College, and Prof. M'Fadyean had reported the growths to be

sarcoma. He did not know whether anything internal had been found.

With regard to rheumatic tendonitis, he had formed the habit of classing rheumatism in the horse with influenza, shoulder lameness, and concussion—very good terms to use. At times, however, a case of tendinous rheumatism was met with.

Some while ago he had in hand the case of a roan parcel horse. The animal had left the stable perfectly sound, but within an hour instructions were received by wire to fetch him in again. The horse absolutely could not walk. He was placed in a box, standing with one hind leg flexed, and was sweating and tucked up. On the following morning he had the other leg flexed in the same way, and for a day or two the lameness changed from leg to leg continually. In a day or two he would fall out sound. He was sent out to work, but after working perhaps a week he had to be fetched in again. He examined the iliac arteries per rectum, as he thought at first that the animal had thrombosis. After a time the sesamoid bursa became enlarged and hard, and the horse was fired on both fetlocks, and blistered.

After a rest the animal was again put to work, and a month later the speaker congratulated himself that the trouble had been overcome. The horse again manifested the same symptoms, and was then sold. Some weeks after Mr. Thompson had seen the horse doing slower work in a dray.

A more recent case was that of a black mare, which, when brought to his notice, had a slight coryza accompanied by a temperature of 102°; she was not eating much. He had directed that she should be placed in the box and given a dose of mag. sulph., believing that she would be alright in a short time. When seen some days later she had developed thick leg, the off-fore fetlock was much enlarged. The leg did not go down under the usual treatment as it should have done, and in about a month she was suddenly very lame in the opposite leg. Apparently there was nothing to account for the lameness. One day he thought he felt a slight swelling over the sheath of the tendon of the extensor pedis above the knee. Two or three days later coagulated synovia was obtained from the sheath, some of the synovia being round and fairly hard, the condition being similar to that occurring with rheumatoid arthritis in canines. The sheath was syringed with a solution of perchloride of mercury 1 in 500. The wound healed, and the mare was now working in a sound condition.

Another case was a chestnut horse, which, after influenza, went suddenly very lame. Nothing could be found in his legs, and tendinous rheumatism, neuritis, etc., were diagnosed, and he remained lame for about six weeks. Eventually, after working for about a month or six weeks the horse came in with ringbone. That had been the termination of many of the speaker's shoulder cases.

Mr. C. H. SHEATHER had personally no doubt of the existence of rheumatic tendonitis, and as Mr. Eaglesham had said, it practically always followed illness of some sort, particularly influenza; it occurred sometimes after strangles. The speaker's method of treatment was different. When he suspected the onset of the malady, the animal was never watered without bicarbonate of soda or carbonate of soda being dissolved in the water, local treatment of course being carried out.

Mr. FOREMAN stated that at one time in his district cases of tendonitis were frequent, but of late years he had not met with it to the same extent. In the early stage of most cases it was hopeless to treat with aspirin or any of the treatments for rheumatoid cases. He had found the disease mostly in imported ponies. Once commenced he had found the cases hopeless so far as

treatment of any kind was concerned, and deformity ensued.

Mr. C. H. SHEATHER referred to a translation from the Italian which he had recently seen, and in which treatment by camphor dissolved in almond oil and ether applied subcutaneously, was suggested. He proposed to try it.

Mr. ALMOND said that while rheumatic tendonitis was common in horses it was even more common in human beings, and in their case there was trouble in dealing with it, notwithstanding more favourable conditions. He thought there was little doubt that the cases were due to an organism in the blood, and of recent years a number of cases had been successfully treated by means of serum obtained by cultivating the organisms from the blood of the sufferer. It would be interesting to make some such experiment in the case of horses, and in view of the fact that research funds were likely to be available, he hoped this would be carried out. During recent years intractable cases in the human subject had yielded to serums provided in the manner described.

Mr. BAYLEY referring to rheumatoid tendonitis ventured to point out that the term rheumatism had been used with some laxity in connection with that subject. It would have been interesting to have had some definition of the pathology of a joint or a tendon which gave rise to that troublesome lameness which sometimes occurred after chest affections. A good few years ago when a pupil he remembered having these cases pointed out to him quite frequently by his principals. He seldom met with them nowadays. In fact he hardly remembered a case within recent years, although some few years ago he was dealing with large quantities of young horses drafted to London from the provinces and Canada that were the subject of all kinds of chest trouble.

Referring to the case of the horse that suddenly became very lame after having been at work for some time, such a history appeared to negative its rheumatoid origin. His own impression was that the lameness in these cases exhibited itself at the very outset of movement, and more or less passed off with exercise.

In regard to subcutaneous sarcomata some owners were apt to put simple but rather awkward questions. They might ask "how did my horse become affected with this dreadful cancerous disease; and was it dangerous to people?" Perhaps someone else would answer these questions. Further, did he understand that the whole of the growths that one saw in the photo were removed from this horse's skin by operation. If so, he presumed the disease was considered to be unlikely to recur; otherwise it would be putting the animal to unnecessary inconvenience—especially as the tumours were not painful and perhaps did not interfere with the harness. The case recalled one of his that presented very similar appearances but the nature of the complaint was different. It had been under treatment for many months, and the owner was becoming tired. The case turned out to be one of a vegetable parasitic nature; the animal was saturated with the suitable agent—really an antidote—and a perfect cure effected in a comparatively short period.

At the suggestion of Prof. Macqueen, and on his motion, seconded by Mr. McIntosh, it was decided to adjourn the discussion on Mr. Eaglesham cases until the next meeting.

A vote of thanks to Mr. Almond for his communication on "Dilated oesophagus in the region of the neck in horses," was then proposed by Mr. McIntosh, and seconded by Mr. Samson. This vote was passed by acclamation, when the proceedings terminated.

HUGH A. MACCORMACK, Hon. Sec.

SOUTH EASTERN VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The ninth general meeting was held at the Rose and Crown Hotel, Tonbridge, on 13th May. The President, E. Lyne Dixon, M.R.C.V.S., of Margate, occupied the Chair, and there were present Messrs. J. Crowhurst, Canterbury; J. Basil Buxton, Herne Hill; G. W. Dunkin, Canterbury; F. Warren, Hadlow; Percy Gregory, Tonbridge; Cecil Crowhurst, Maidstone; T. F. Hogben, Ash; H. P. Hogben, Folkestone; Charles Roberts, D. Reed Chalmers, Tunbridge Wells; J. M. Richardson, Deal; J. H. Ripley, Hurst Green; E. W. Morris, Uckfield; Elmer Ebbetts, Rochester; Wm. Caudwell, Chertsey; and Theo. C. Toope, hon. sec., Dover.

Messrs. J. C. Coleman (President of the Royal Counties), Hugh A. MacCormack (Secretary of the Central), and Mr. R. S. Stow, Hadlow, were present as visitors.

Letters and telegrams were received from the following regretting their inability to be present: Messrs. T. Hibbard, W. Shipley, A. T. Crowther, G. Fordham, H. W. Caton, Prof. Wooldridge, W. R. Emery, E. Morgan, H. C. Golledge, E. M. Perry, C. J. Callow, Major Edwards, J. C. Munby, W. Burt, J. B. Martin, F. G. Samson, J. Washford, A. H. Archer, R. Thrale, C. Morgan, T. A. Huband, A. Whicher, W. Clifford, David Pugh, W. W. Gulleford, J. B. Dier, and J. McIntosh.

The minutes of the last meeting were adopted as printed and confirmed. Mr. Toope explained the reason for the absence of much of the matter.

Mr. A. T. CROWTHER, Deal, was elected a member of the Association on the motion of Mr. Richardson, late of Deal, seconded by the Secretary.

Correspondence.

Mr. TOOPE: You will remember that at our last meeting the question of the National Congress and a subscription thereto was mentioned, and in order to go into our financial position, for it was impossible for me to then say what it was, it was decided to leave the matter over until this meeting, and also for another reason, to give the officials of that Congress the opportunity of replying to some letters written by Mr. Crowhurst, which I propose shall not be discussed again to-day. We had a Council meeting on Saturday week, and we came to the unanimous conclusion that we would entirely ignore subsequent letters from the Congress. We simply are treating them exactly in the way they have treated our late President. They have ignored his letters, and consequently the Council declined to do anything with regard to any future letters from them. I have another letter asking for a subscription from the Society, and also suggesting that if we elect a representative from the Society we should pay a guinea or one pound in addition. I think the Congress has become almost beyond reason in its begging attitude, and I believe the Council think so too.

The PRESIDENT: I regret very much, as a member of the Council, that owing to the way in which they have treated our late President we have felt bound to decline to have any official connection as an Association with the matter of the International Veterinary Congress which we were all looking forward to during this year. It does not, however, in any way prevent members individually of this Association supporting it, and I trust they will do so as far as lies in their power. It is the first time the National Congress has been held in this country, and I think we as a rising profession should individually endeavour to make it a success. Personally, I shall do so, and give my private subscrip-

tion, and I think it is only right to do so without going into the controversy which has taken place.

HUNTING PETITION AND SUBSCRIPTION FUND.

Mr. TOOPE: The President of the Royal College of Veterinary Surgeons has asked the President of each Society to sign the petition on behalf of the children of the late Mr. W. Hunting, a very esteemed member of the profession, and whose death has caused a great loss to us.

It was decided that the President should sign the petition.

PRESIDENTIAL ADDRESS.

Mr. E. LYNE DIXSON.

Gentlemen,—This being the first occasion upon which we have met since you unanimously appointed me President of this Association. I have pleasure in adopting the usual course at meetings of this kind by addressing a few remarks which I trust will be of interest: but before doing so let me again thank you most sincerely for the honour conferred upon me, and the confidence reposed in me by your selecting me as your President. I assure you I will endeavour to carry out the important duties appertaining to the office with honour and dignity both to myself and the Association I represent.

With your permission it is my intention first to take a general retrospect of the S.E.V.A. and the work accomplished since it came into existence. Our Association was formed on Jan. 31, 1912, at a meeting of veterinary surgeons of the County of Kent, convened by our worthy Secretary, Mr. Toope, as a result of a private conversation between him and Mr. James Crowhurst, of Canterbury, who was ultimately our first President. Both these gentlemen thought a meeting of veterinary surgeons of the county should be called to consider the advisability of forming themselves into an Association, and whether that opinion was justified I will leave you to judge by the subsequent course of events. Mr. Toope then wrote to every gentleman on the Register in the County asking his opinion, and from the very encouraging nature of the replies, he resolved to at once call a meeting, which was held at County Hotel, Canterbury. There were present Messrs. James Crowhurst, W. H. Crowhurst, and G. Dunkin, of Canterbury; T. W. Cave, Ashford; Elmer Ebbetts, Rochester; F. C. Gillard, Folkestone; E. Lyne Dixon, Margate; F. T. Hogben, Ash; T. A. Huband, Wrotham; T. Hibbard, Gillingham; the late R. Roberts, Tunbridge Wells; and T. C. Toope, Dover. Mr. J. Crowhurst was unanimously elected President, and Mr. Toope, Hon. Sec. and Treas. Four Vice-Presidents were also elected, and the business of the meeting duly commenced. First the question of fees was discussed, and great dissatisfaction expressed regarding them. It was then resolved to invite all veterinary inspectors in the County to attend the next meeting whether they cared to join the Association or not. Thus began the first organised attempt to better conditions in Kent, which, having been carried to a successful issue during the first full year of the Association's existence, after an immense amount of clerical work on the part of our Hon. Sec., more especially in ascertaining and tabulating the fees paid by all the counties throughout the United Kingdom. It was then carried on by Mr. Toope to the National Veterinary Association's meeting at Manchester, who adopted the scale provisionally (practically without alteration) after its re-consideration by a special Committee of the Southern Branch of the Association. From there it was circulated amongst all the affiliated societies in the kingdom, as a basis for negotiations to local authorities, with the result that in very many instances their fees have been largely augmented, Kent having the undisputed credit of pioneering the good work.

Commencing with 12 members we finished the year with 40 in number, which was increased to 57 during the past year. We have to deplore the loss of two eminent members, viz., the late Mr. Wm. Hunting, London, and Mr. R. Roberts, of Tunbridge Wells, both of whom had gained the esteem and respect of the whole of the members of the veterinary profession. Mr. Roberts was one of the founders of the Association, and was a gentleman whom we could ill afford to lose, and he was a regular attendant in our midst.

Much of the success of this Association is undoubtedly due to the inception of the Veterinary Inspectors' Section, held prior to our general meetings, to consider matters of interest appertaining to their duties, and I would suggest that other societies would do well to follow on the same lines.

The next important subject taken in hand by the Association was the absurd fees paid to veterinary surgeons by insurance companies. After a great deal of discussion a scale of fees, prepared copies of which were submitted to other Societies, and generally met with approval. The same course was then adopted as with veterinary inspectors' fees for municipal and county work. They were submitted to the Southern Branch of the National by our Secretary. A special committee was appointed to revise them. The revised scale was brought before the General Council, who adopted them and empowered the Sub-committee to further act, with the result that in a few days now all members of affiliated societies will be advised to accept nothing less than the prescribed scale of fees. The long delay in this matter has been almost entirely due to the policy of procrastination the insurance companies adopted, which necessarily entailed a lengthy correspondence, but will eventually be a source of monetary gain to a large number—if only members of the profession will be true to themselves, and to those who have worked in the matter, by absolutely refusing to accept remuneration only on the scale recommended.

Another innovation at the later meetings held by this Society was the introduction of interesting pathological as well as microscopical specimens. Papers and addresses have also given food for discussion during the past year, amongst which were the President's (Mr. Crowhurst) Presidential address, a paper by itself on "The Relationship of the Board of Agriculture to the Veterinary Profession," Mr. Elmer Ebbett's paper on "John's Disease, a *resumé* of the Tuberculosis Order," which elicited much discussion, and we had a very interesting paper by Mr. Caudwell—"Notes on Twenty Cases of Tuberculosis," also a demonstration by Mr. Buxton at our Maidstone meeting, showing the method of isolating bacillus of tuberculosis in milk, for which the thanks of the Association are due.

Eight general meetings have been held, and as many committee meetings, the average attendance being 16 the first year and 26 the second year. Ladies have been present at both our annual dinners, and one of our summer meetings, which is now to become a regular custom. Socially this has been no unimportant element in our success. Apropos of this subject, I may say in passing that the Committee have decided to hold our next meeting at Margate in September next, and as your President I trust I shall have the pleasure of welcoming and entertaining as many of the members and their lady friends as can conveniently attend on that occasion.

In concluding our retrospect of the Association I should like to allude to the financial aspect. Our expenses are somewhat heavy, but our Secretary informs me that there is a balance of £14 or £15. I must also allude to the support of members from East Sussex and Surrey. I trust they will not only continue to support us Kentish members, but endeavour to induce other practitioners to do the same, and so by an accession to

our ranks the name of our Association, viz., the South Eastern Veterinary Association, may be truly and amply justified.

I trust I have not wearied you by this *resumé* of the work which our Association has accomplished. Personally, I consider it a source of pride and congratulation that out of such small beginnings, but a short two and a-half years ago we should have attained the satisfactory conditions we have to-day. To what cause can this state of affairs be ascribed, and to whom is the credit to be given? I am of opinion that it is due to two causes. Firstly, to the members of the Association themselves who have so loyally and in such numbers attended our meetings, many at long distances and at great inconvenience, and thus showing that they take an active and lively interest in the Society's welfare. It is only by enthusiasm and whole-hearted loyalty to ourselves and to each other, with a watchful and jealous eye on the interests of this Association, that we can hope and expect it to prosper. Let us not content ourselves with standing still and being inert because we have succeeded beyond our expectations, but let us continue, each one individually, to make the further success of our meetings assured, and this we can do by:—

Firstly. Regular attendance as far as possible, at our gatherings, even if at the sacrifice of our personal convenience.

Secondly. By bringing forward records of interesting clinical cases for the instruction and information of our professional brethren, and

Thirdly. By cementing the good fellowship that should, and I believe does exist amongst the individual members, and which but for the formation of this Association, would never have existed.

Now what is the second cause of our success? I say without fear of contradiction that it is in a very large measure due to the unequalled energy, grit and perseverance thrown into his work by our Hon. Secretary, Mr. Toope. His secretarial abilities are so patent to those who observe, that it is needless for me to enlarge on them, but let credit be given where credit is due, and I say, we as an Association are indeed fortunate to possess a secretary so painstaking, thorough, and enthusiastic as Mr. Toope, and I take this opportunity of thanking him on behalf of the members of this Association for the prodigious amount of work that he has done so willingly and ungrudgingly since its inception.

Gentlemen, we are on the eve of the election for members of the Council of the R.C.V.S. and Mr. Toope, our Secretary, is a candidate, and having gone into this matter of representation on the Council, I wish to draw your attention to the following facts which are approximately correct. In the counties South of the Thames (excluding London and its immediate district), there are 425 practitioners represented by two councillors. In the counties represented by the Southern Branch of the N.V.A. there are about 800 exclusive of London, represented by four councillors, viz.: Messrs. Burt, Dunstan, Shipley and Banham. This number constitutes over one-third of the whole of the members residing in the United Kingdom. Yorkshire numbers 184 members, represented by six councillors; Lancashire 186 members represented by four councillors, and a would-be fifth. London, with immediate district, 229 members with eleven councillors.

Surely, gentlemen, this cannot be held to be a fair representation! Of the six Yorkshiremen, five are, I believe, members of the Yorkshire Society, and four actually live in or close to Leeds. My idea is that every separate Society should return at least one member, unless exceptionally large, then two. The reason for the excessive number in the North is the excellent organisation of the Societies, and every credit is due to

those gentlemen for the interest and zeal that many, from my own personal knowledge and observation, take in the welfare of their profession. But that is not the point. It is merely a question of fair and equitable representation, and I appeal to not only members of this Association but to other Societies to support the candidature of our friend and Secretary, Theodore Toope, who is an enthusiastic worker, and who will look after the interests of the rank and file of the profession, more especially the country practitioner.

I have dealt so lengthily with taking a retrospective view of our Society and its work, that I fear I can devote little space to a prospective point of view; but I feel bound to allude to what appears to me to be a few important matters that might mutually be discussed to our general advantage. They are: Exemption from serving on Juries: Rebate of the Petrol Tax: Discussion on whether some means could be found to minimise, if not put an end to, the lamentable differences of opinion that occur in our Police Courts. It is a matter I feel very strongly upon, because in many cases (and I am not referring to those where possibly genuine differences of opinion may exist), but to those where there are one or perhaps two, veterinary surgeons on each side swearing diametrically opposed opinions on even the question of whether a horse is lame—one side saying a horse is lame and unfit for work, and the other side that he is sound and fit for work. I say this should not be, as there is only one conclusion to come to—either wilful misrepresentation or lamentable ignorance of the very elementary details of their profession. It therefore behoves us as a Society, should such glaring example come before any of its members, to bring the matter forward for discussion.

I well remember a County Court case I was on, in conjunction with another veterinary surgeon, we appearing for the plaintiff (who had purchased a horse from the defendant) for the return of money paid for an animal warranted, which had a side-bone. The warranty was written on receipt and admitted. There were two veterinary surgeons on the other side, both of whom swore there was no side-bone and that the animal was sound. The Judge summed up shortly in these words, "This is a case where the warranty is admitted, but we have two veterinary surgeons on each side swearing diametrically opposed opinions as to soundness, and I have therefore to decide which in my opinion is speaking the truth. I therefore give a verdict for the plaintiff with full costs." Gentlemen, comment is needless.

There are many other questions I could touch upon which are all important to us as veterinary surgeons, but we have now the pleasure of listening to Mr. Morris's paper. "Immunity as it affects the Provincial Veterinary Surgeon." After which I invite discussion, should time permit, both on the presidential address you have listened to and on Mr. Morris's paper for which we thank him in anticipation.

I must now gentlemen, thank you for your patient hearing, and trust some little instruction and information will be gained as a result of the discussion which I trust will follow.

Mr. TOOPE: I think it is my duty first of all to thank Mr. Dixon for his high praise of me as Secretary. I feel I cannot resist the temptation to rise at the first moment. I scarcely think, perhaps, I am quite worthy of all he has said. I have done my best, and I shall continue as long as I can to justify the position I hold. That is if you will have me. There is another matter which I wish to allude to, and it is the candidature for the position on the Council. I may say, as you all know, last year we had the same views as we hold to-day. It is that the country practitioner is insufficiently represented. We proposed our late President, Mr. Crowhurst, and we did our level best as a Society, and

personally I did the same to secure his return on that occasion. This year we again proposed him at the last meeting but, unfortunately, Mr. Crowhurst was then in family trouble, and unable to continue his candidature, and at the last moment practically, I was asked to take his place as being long associated with him in this matter of inspectors fees and insurance fees. I shall in this case be associated with Mr. Coleman, of Swindon. He and I have similar views on most things connected with the profession, and personally, I am quite sure whether he goes first, I shall be near him as a second. If I tackle the thing I am pretty certain he will second it in the same way. If we were as well organised as Yorkshire and Lancashire, we should return a member for every Society, say two, in the South of England. What it wants is organisation. I must thank Mr. Dixon again for the kind allusion he has made to me as Secretary and Treasurer, but I cannot quite forgive him for he has repeated it two or three times. Those who vote for me I trust will also, I hope, vote for Mr. Coleman.

Mr. CROWHURST: I think I too have a duty to you to thank you for your kindness in recommending me as a candidate for the Council of the R.C.V.S. At the time I did say I would stand for election, but, as it has already been stated, I met with a sad affliction in my family, and there were also other reasons. I felt that there was some antagonism in consequence of this unpleasant matter in connection with the National Congress, and I felt that if I succeeded in gaining the position of honour you were willing to offer me, there would be some antagonism in the Council in consequence of this, and the unpleasantness would not be conducive to the interests of the profession or the Association. I hope most earnestly we shall do our utmost to get Mr. Toope returned.

The PRESIDENT: I wish to refer to the question of the forthcoming election. We have met Mr. Coleman for the first time to-day, and I think it is right that we, as an Association, should do as Mr. Toope suggested. It does not matter so long as we get well represented. If we couple Mr. Toope with Mr. Coleman, and Mr. Howard of Ireland, and ensure that they get in, we shall be doing the right thing. I can see that Mr. Coleman is a man who can express his views, and is not afraid to express them. They are the sort of men we want.

Mr. COLEMAN: I would like to tell you that for the last twenty five years I have been particularly interested in public health matters in urban, county, and borough departments. It has been my ambition to bring veterinary surgeons to the fore front on every occasion. At a Congress at Bristol in 1906 a resolution was proposed that sanitary inspectors should be employed for the inspection of public abattoirs, and I was the only veterinary surgeon present who proposed an amendment to the effect that it should be done by veterinary surgeons, and my amendment was carried. You may rest assured if I have the honour of being elected, my sole object will be to improve our present professional and social status.

Mr. CAUDWELL proposed a hearty vote of thanks to the President for his interesting and comprehensive address.

Mr. ROBERTS seconded

Mr. CROWHURST: I should like to speak in support of that. Mr. Dixon brought a very weighty matter before the profession wherein he has shown us that we can do a great good to our profession by being more careful in the opinions we express in Court. A disparity of opinion in police court cases brings but very little credit to the profession. I hope that one and all will take it to heart. There is room for considerable improvement in these matters of court business. It is

one in which we are held up to ridicule by judges, and it should not be.

Mr. CHALMERS: I am quite in sympathy with Mr. Crowhurst. It makes my blood run cold when I read in the newspapers of one veterinary surgeon cross swearing another. I am pleased to say that in this district we have no trouble in that way. The jury often is a very serious one. It is a great waste of time, and there is no remedy whatever.

Mr. CROWHURST: I would rather be judged by my brother professionals at a meeting like this, because they would understand the difficulties. A judge's knowledge is only book learning. He really cannot understand the same as a veterinary surgeon. Justice would come out of it very much better, and it need cause no friction at all.

The HON. SEC.: When this Association was formed it was one of the duties specially given to the Council to discuss such cases, and we should have adopted this system had we the opportunity of carrying it out.

The PRESIDENT: I take it the best thing would be for some one at a future meeting to put it on the agenda for discussion, and take some definite and proper action as to what we can do.

BALANCE SHEET.

The TREASURER: At the present time we have a balance in the bank of £14 17s. 10s., and we have outstanding about £6 6s. The balance has been enhanced and the outstandings considerably reduced. The result of two years' working leaves us a balance in hand of practically £20.

INSURANCE FEES.

The HON. SEC.: Nearly two years ago we started a discussion on the fees of the insurance companies. The National Association appointed a Committee for the purpose of dealing with it. They met three or four times and eventually drew up a scale of fees which we submitted, first to the National Association who referred consideration of details to the Council of the National Association and a Committee who had power to act. So that what we have done now is practically the action of the National Veterinary Association as a body. I have had considerable difficulty in dealing with the companies. Their method has been one of procrastination throughout. I have not only had correspondence with various insurance companies, but I have seen two or three managers, and this is the outcome of all our work and all our efforts. A conjoint offer of 4/- for the examination of any horse and report, value £100, with an additional 2/6 for a second one, and half that sum for cattle, with a maximum of £2 2s. for 20 head, all mileage and other charges to be included. That was absolutely rejected by the Council of the Association and they have drawn up the following scale which I ask this Association to adopt. [*This scale is set out on p. 755*]. Since then they have been ratified by the Council of the Association. We want to make it a universal system, and they are somewhat less than the fees we first suggested. It is for us, as we have taken the lead in this matter, to keep it, and I propose that we to-day accept this particular scale. I know this will not be acceptable to all. We have absolutely declined to accept less than 5/- in any case instead of 3/-, which we get now. We can enforce these fees in a very quiet way, and the beauty of it is they know it. We have only to transfer any business we have with the Manchester and Underwriters' Association, and we shall immediately force other societies to accept, or the Manchester and London Underwriters' Association will get practically the whole of the insurance business in Britain.

Mr. WARREN: I second the proposition, and quite endorse what Mr. Toope has said,

Mr. CAUDWELL: We are not all members of the N.V.A., but those who are members of it should adopt the fees suggested. There are no doubt plenty who will regard 3s. as worth earning when looking for a further source of income.

Mr. CROWHURST: The Manchester Underwriters are ready to accept the work at a better fee altogether, and why not recommend the clients to go to them and ensure there. I know of a case where an unqualified man was sent to examine a horse and it died, and the Insurance Company refused to pay any compensation because their rules had not been complied with by employing an unqualified man. I think if we accept this scale of fees as a beginning, it will be a great improvement on the past, and you are not bound to go on if you find you can get better terms.

IMMUNISATION AND THE COUNTRY VETERINARY SURGEON.

By E. W. MORRIS, M.R.C.V.S., Uckfield.

Mr. President and Gentlemen,—The idea of fighting bacterial infection by those defensive agencies which the organism itself employs when it contends with an invasion must be a sound one, but the question I want to discuss with you is—Is it possible for the country veterinary surgeon to employ these methods in his every-day practice with safety? I think it is, in those cases of localised bacterial infections which are of such a nature that the clinical observer can immediately see for himself or learn of every change in their condition.

The most typical examples of such infections are poll-evil, fistulous withers, abscesses, and wounds where chronic conditions exist.

I have no doubt that a good many of us have come to the conclusion that antiseptics are not effective in stopping bacterial infections. Antiseptics can only take effect upon those bacteria with which they come in contact, it is obvious that the infecting bacteria will not all be lying on the surface, and it is unreasonable to expect to kill them all, a residue will survive, and multiply and reoccupy the disinfected surface. The antiseptic also directly acts against the protective forces which the organism has at command—it will paralyse the phagocytes and abolish the anti-bacterial power of the blood fluids, it will injure the tissues, especially the capillaries, and will thus lead to an outpouring of lymph which will wash it away.

If we believe this we must look round for something better; it is no good adopting the expectant treatment of sitting down and waiting for auto inoculation, as in localised bacterial infections this does not take place, the focus of infection being more or less cut off from the circulating lymph by infiltrated tissue; and it is only perhaps when life itself is threatened that Nature addresses herself in a serious manner to the task of immunisation.

Let us first consider the protective forces of the organism. The leucocytes are capable of ingesting bacteria, and disintegrating them by intracellular digestion.

Sir A. E. Wright distinguishes between spontaneous and induced phagocytosis. The former term is applied to that process of digestion which comes under observation when bacteria which have not been subjected to the action of the blood fluids are brought in contact with washed leucocytes in an indifferent medium, such as weak salt solution. It is a slow process, only a few bacteria being digested, and the digestion is irregular, the leucocytes differing very largely in their intake of bacteria. It is completely stopped by a 1% solution of salt—in the case of the tubercle bacillus at any rate.

Induced phagocytosis is strikingly different. Here leucocytes are brought in contact with bacteria which have been, or are subjected to the action of the serum. It is an exceedingly rapid process; every adult leucocyte assists—will fill itself to absolute repletion, and will continue to do so even in salt solution which would stop spontaneous phagocytosis.

The anti-bacterial elements of the blood are assumed to be four in number.

Bactericidins kill the bacteria without dissolving them.

Bacteriolysins kill and dissolve them.

Agglutinins clump them up together in the presence of salt.

Opsonins so alter them that they are easily ingested by the leucocytes.

Of these four the opsonins are the most important, because either in normal or immune blood they affect every kind of bacteria, and they can be accurately measured whether they be increased or reduced. We now know that the increase of these opsonins is correlated with clinical improvement.

In cases where we know the infecting microbes and the required vaccine, and when the proper dosage has been worked out and made known, treatment by vaccine may be undertaken successfully with no more technical skill than is required for the administration of a dose of arecoline. But unfortunately, in most cases the nature of the infection is uncertain, and any bacteriological examinations must be continually revised, as new microbes may invade the wound and those originally present may disappear.

Assuming we know the required vaccine the required dose is again a difficulty to the country veterinary surgeon. Sir A. E. Wright regulates the dosage by taking an estimate of the opsonins in the blood; this estimate he calls the opsonic index.

1. Where an examination of the patient's blood taken 24 hours after inoculation shows that this index is considerably reduced too large a dose has been given.

2. Where an examination of the blood 24 hours after inoculation shows that the index has been raised, and where after the expiration of a week the index has fallen back to what it was before inoculation, too small a dose has been given.

3. Where, in association with a slight initial fall after inoculation, the index is after the expiration of a week found to stand higher than it was at the outset the proper dose had been administered.

This is no good to the country veterinary surgeon, but, as we have said before, a rise in the opsonic index is correlated with clinical improvement, and *vice versa*.

Now apply this, let us say, to a case of poll-evil. Taking the first case, where too large a dose has been given, at 24 hours the animal would be disinclined to feed, the head would be carried more stiffly than usual, the internal temperature raised a degree or two, there would be an increased discharge of pus from the sinus and this pus would be thinner than before.

In the second case, where too small a dose has been given, there would be no constitutional disturbance, the discharge would be less and thicker, but things would be soon back in the old place again.

Where proper dose has been given, first there would be a slight rise in the internal temperature, the animal would probably refuse one meal, or some of its food (I had one horse that always refused it hay at night when injected at midday), the discharge from the sinus would increase and become thinner, at 24 hours it would be flocculent, gradually getting thicker and less abundant, the movements of the head would be more easy, and appetite improve. This general improvement should be maintained by another dose of vaccine in a week.

It is one thing to assert that it is very often possible for the immunisator to be able from the clinical symptoms to obtain information which will assist him in selecting his doses and interspacing them. That such help can be obtained is a self evident truth, but that these symptoms will in every case inform him whether the proper quantity has been given is quite another thing.

In the clinical result we have only the terminal event in a long and intricate chain of causation, and whether the result is improvement or the reverse it is due to many factors of which the achievement of a satisfactory immunising response is only one; it would profit a patient nothing to have responded to an inoculation by an elaboration of anti-bacterial elements, if from any cause the antibacterial agencies which were at disposal in his blood failed to reach the invading bacteria. Nor would it profit the patient anything in his struggle with disease if his machinery of immunisation responded to every call while some other essential part of his physiological machinery gave out.

The bacteria usually associated with chronic suppurating conditions like poll-evil are first staphylococcus albus, but my observations lead me to believe that in all old standing cases we have secondary infection with staphylococcus aureus and citreus and streptococci; so why not begin with the mixed vaccine? Of course it is probable that the best results will follow the use of a vaccine made from the individual patient, but stock vaccines give good results, and can be tried or used until an autogenous vaccine can be obtained.

The initial dose should contain five hundred millions of staphylococci and one hundred millions streptococci; their origin should be from the same species of animal as the patient, and the vaccine should be polyvalent. It should be injected near or around the focus of infection.

No advantage is reaped by piling one inoculation upon another, with the idea that it must be possible to achieve a greater yield of protective substances by employing successive doses of vaccine increasing enormously. Such a system if persisted with must end with disaster. Never advance to a larger dose until it has been ascertained that the dose which is being employed is too small to give adequate immunising response. Five to eight days seems about the time that should elapse between the inoculations.

Again taking poll-evil as an example, let us see the conditions present. Leucocytes disintegrate in the focus of infection—and they will die and disintegrate not only under the influence of bacterial toxins which are generated, but independently of this there will be liberated larger and larger quantities of tryptic ferment until finally the antitryptic power which the lymph possessed when it transuded from the blood vessels is overpowered, the connective tissue breaks down, any fibrin which envelopes the leucocytes is dissolved and an abscess sac formed; the fluid, which is more or less shut off from the circulating lymph by infiltrated tissue, forms a nidus for bacterial growth. In these circumstances the lymph in the abscess sac, which originally possessed anti-bacterial and antitryptic properties, becomes first impoverished in anti-bacterial elements, then loaded with bacterial products, and finally endowed with tryptic properties. It will be clear that fresh leucocytes, should they arrive on the scene and escape paralysis by bacterial toxins and digestion by the tryptic ferment, find no opsonic substances in the abscess to co-operate with them.

The pus fluid will now proceed to eat into the surrounding tissues and, owing to the anatomy of the part, burrow in depth before it points upon the surface or is opened, and eventually we have a sinus discharging pus. The pus in such a case possesses a low opsonic power,

it is charged with bacterial toxins, contains a tryptic ferment, and often from the nature of the part it cannot be properly drained.

Now we are aiming at the destruction of bacteria by the agencies of opsonins and leucocytes, and also aiming at the same time at the safeguarding of the tissues from the digestive action of the pus. It would be futile to attempt this task without making provision for the replacement of the tryptic and non-opsonic pus fluid by antitryptic and opsonic fluid freshly derived from the blood. We know that a deficient flow of lymph and the formation of fibrin on the walls of a sinus favour the survival of the infecting bacteria, so these conditions should be combated by the introduction into the sinus of a solution of salt and citrate of soda. The citrate of soda prevents the coagulation of the lymph, and the salt solution by osmosis causes fluid to transude from the blood vessels. Under this application clear lymph wells out, and local conditions improve.

Every now and then this treatment should be stopped for a time so that improvement, or the reverse, can be more easily noted. The only antiseptic used in these conditions should be weak boracic acid solution.

Don't think I am condemning all time honoured modes of procedure. Sometimes the intelligent use of a probe-pointed bistoury, or one caustic application to slough out the bacteria laden walls of the sinus may be necessary to bring about the condition I require, and of course any dead tissue must be removed.

In other cases of bacterial infection—local infections, hidden from clinical observation, or those grave septicæmic infections where vast auto-inoculations are going on, how is it possible for the country veterinary surgeon, in the absence of laboratory methods, to undertake vaccine therapy without courting disaster?

However, upon the country veterinary surgeon of the future, when he shall have been trained in the physiology of immunisation as he is now trained in the physiology of the circulatory and digestive system, will devolve the task of directing such antibacterial agencies as may be available in the patients' blood to the destruction of microbes in local infections. When he comes to regard it as his function to minister to immunisation he will not, in the case where he has to deal with infiltrated and infected tissues, stop short at mere incision and drainage, but will work to secure that free lymph flow through the focus of infection which is essential to immunisation. When he has to deal with a suppurating focus he will not rest satisfied with evacuating pent-up pus, but will recognise that such evacuation contributes only to the extinction of the infection in such measure as it serves to bring the antibacterial agencies of the blood into effective operation upon the microbes. And again, where he has to deal with a wound which refuses to heal, or with a wound which is pouring out day by day a wholly ineffective pus, he will realise that what is required in such a case is an increase of the antibacterial power of the blood and a more effective lymph flow, such as would bring the antibacterial agents of the blood into active operation upon the infecting microbes.

We must anticipate that the methods of increasing the antibacterial power of the blood will be constantly improved while better methods of measuring those antibacterial elements will be devised. Meanwhile we have gone far enough to see that we have the power of increasing the antibacterial elements of the blood by the agencies of vaccines.

I have quoted the author of this treatment, Sir Almoth E. Wright, consciously, unconsciously, and subconsciously, and I think the debt we owe him as veterinary surgeons is as great or greater than that we owe to Lister. The debt we owe him as human beings is so great that I will not attempt to compare it, because, as he says, "the really serious ills of life are those

various localised bacterial infections which sooner or later fasten on every man, never afterwards releasing their hold."

A very interesting discussion ensued in which Messrs. Buxton, Warren, Duncan, Hogben, Gregory and the Secretary took part. (This was altogether too technical for my reporter. T. C. T.)

Mr. MORRIS said in reply: I am apparently attacked on three points—1st, Mr. Buxton states it is not necessary to inject the vaccine near or around the focus of infection, although he states it can do no harm there. I will tell you Sir A. E. Wright's ideas on that point, and allow you to judge for yourselves. "A whole array of observations point to the local production of bacteriotropic and vaccinatropic substances generally at the site of inoculation. If we may build on the aggregate of these observations it would logically follow that the site of every inoculation deserves to be carefully considered," Mr. Buxton said it did not matter when such injections were made. I contend that when protective substances pass into the blood through a channel which does not lead them through the focus of infection, the newly elaborated antibacterial substances will come into operation on that focus *only after* they have become diluted by the whole volume of blood (if I may so express it) *up stream* from the focus of infection, that is in some part of the lymph watershed which drains through the focus of infection. The antibacterial substances which are produced at the site of inoculation come into application upon the focus of infection in a concentrated condition. Wright proves this by recording cases which only improved when inoculations were made near and around the focus of infection.

Mr. Dunkin and Mr. Warren discussed serum treatment, in which I do not place implicit faith. Sir A. E. Wright's ideas on sera may be summed up as follows: "No serum does much good unless there is a certain amount of reaction; immune serum of itself will not give any reaction. If it gives a reaction it contains bacterial toxins, so that it is a vaccine in reality and not a serum. The doses of the vaccine under the mask of a serum cannot be fixed because no two samples of such contain the same amount of bacterial toxins, and some none at all, hence most all will eventually be replaced by vaccine.

The third point: The tryptic properties of pus are proved conclusively, and account for burrowing in poll-eil and other diseases.

One point now occurs to me, secondary invaders must be dealt with. Scott is insistent on this, and with him I agree. Therefore use a mixed vaccine and try to kill these off before they get established—prepare for them in fact.

The PRESIDENT: I desire to move a vote of thanks to Mr. Morris. We have received a good deal of instruction from the discussion which has arisen. [This was carried.]

The PRESIDENT: I also wish to move a vote of thanks to Mr. Crowhurst, our ex-President, for the able manner in which he has fulfilled the duties of office for two years.

Mr. MORRIS: I second that. Mr. Crowhurst was always willing to help everyone in every way.

This was unanimously carried.

Mr. CROWHURST: I have very great pleasure in accepting your good wishes in hearty response to the President. I have been amply repaid for anything I have done by the kindness and support I have met with from every member. I have sometimes spoken earnestly on questions brought forward, questions which have embraced many subjects, and I am glad to find that they have been taken up with zest and good will, and carried to fruition. I thank you very much indeed for

your kindness in every way, and I accept your kind proposition with the greatest gratitude possible.

The PRESIDENT: The next meeting is to be held at Margate in September, and I extend an invitation to yourselves and lady friends. I shall do all I possibly can to make you quite happy, and entertain you to the best of my ability.

In the Microscopic Section, Mr. Toope exhibited a milk smear from a cow suspected of tuberculous induration of mammary gland, but found to be due to streptococci in immense numbers. Smears from lung of cat showing tubercle bacilli, also smear from lung of horse showing tubercle bacilli, and others. Several interesting post-mortem specimens were also exhibited, including the pulmonary organs of a cat showing miliary tuberculosis in the varied stages. This being the third cat in the same street that came under Mr. Toope's notice during the first half year found to be suffering from tuberculosis on post mortem. The milk supply in each case being from the same source suggests a common cause possibly, especially so as it had been found to contain tubercle bacilli some months previous.

A vote of thanks to the President closed the proceedings.

THEO. C. TOOPE, Hon. Sec.

ELECTION ADDRESSES.

To the Fellows and Members of the Royal College of Veterinary Surgeons.

Gentlemen,

I beg to offer myself as a candidate at the coming election of Council.

My views on veterinary politics are, I think, fairly well known to many, and I need not refer to them in detail; it is sufficient to say that I am a strenuous advocate of any measure which will tend to improve the status of the members of our profession.

I am strongly in favour of the Veterinary Surgeons Act Amendment Bill.

The wide field now opening in Veterinary Public Health is to some extent indicated in the Milk and Dairies Bill now before Parliament, and should you do me the honour to elect me as one of your representatives, I would at all times do my utmost to safeguard your interests.—I am, gentlemen, your obedient servant,

J. W. BRITTLEBANK.

To the Fellows and Members of the Royal College of Veterinary Surgeons.

Gentlemen,

At the request of the members of the South Eastern Veterinary Association, I am seeking your suffrage as a candidate for the Council of the Royal College at the ensuing election.

I am in favour of maintaining the educational standard of our graduates, and believe much time could be saved and increased efficiency in vital subjects obtained, without increasing the period of study by insisting on some of the minor elementary science subjects being made part of the matriculation examination.

I should favour any scheme brought forward to obtain State aid for our teaching schools, especially for research work, which in my opinion we should retain as far as possible.

Our financial position is alarming, and renders the Veterinary Surgeons Act Amendment Bill a pressing necessity.

If honoured by election any measure calculated to benefit the general body of the profession, will receive my support.

I am, gentlemen, very obediently yours,
THEO. C. TOOPE.

Death following the External Application of Kerosene.

The following case is reported in the *Australian Medical Journal* of February 7th by Dr. J. K. Adey. A man, aged 73 years, had been in an asylum for three years in consequence of senile dementia. An attendant noticed some vermin in the axillæ, into which he swabbed, but did not rub, kerosene. Some of the liquid ran down the patient's sides into his groins. The kerosene was not washed off and the patient was clothed in a flannel, a shirt, and outer garments, and was seated in a chair in the sun. Seven hours afterwards he was seen by one of the medical officers in a collapsed condition. Large raw surfaces extended from the axillæ to the groins and there was a raw surface in the lumbar region about 4 by 6 inches. Some of the kerosene evidently had run behind his back. The condition was one of superficial burns for which he was at once treated, but he gradually sank and died three days later. It is remarkable that kerosene, which is frequently used as an external application, should have caused such rapid denudation of the skin. The cuticle had peeled off the affected areas. The severity of the result was probably due to the clothes being put on over the kerosene, which prevented free evaporation and the heat of the sun seemed to have aggravated the effect. There seemed no possibility of the kerosene being contaminated as it was drawn directly from the tin supplied by the dealers. The necropsy showed that there was no internal lesion and that the patient, considering his age, was in good physical state.—*The Lancet*.

Personal.

Mr. WILLIAM PENHALE, M.R.C.V.S., has been elected Chairman of the Holsworthy Urban District Council for the third year by a unanimous vote.

SILVER WEDDING.

Mr. and Mrs. SYDNEY H. SLOCOCK, Springcroft, Montague Road, Hounslow, married at St. Stephen's Church, Hounslow, May 15th, 1889, by the Rev. Henry Layton, M.A., Vicar.

OBITUARY

Major William Martin-Millar, F.R.C.V.S., A.V.C.

It is with great regret that we have to record the sad death of Major William Martin-Millar, F.R.C.V.S., Army Veterinary Corps, at Lucknow, India, on the 25th April, 1914, from smallpox, after a very brief illness. The deceased was Divisional Veterinary Officer of the 8th Division and had been stationed at Lucknow since November, 1913. He landed in India on the 2nd Jan., 1912, and would have completed his present tour of foreign service on the 2nd Jan., 1917.

Major Martin-Millar was popular with all ranks, and had made many friends during his 18 years service in

the A.V.C. He was a keen veterinary practitioner and an exceptionally good judge of horses.

He was buried at Lucknow on the 26th April with the full military honours of his rank. The funeral was attended by almost every officer present at the station. Wreaths were sent by all the regiments and units forming the Lucknow garrison, and by a large number of friends, officers, non-commissioned officers, and men.

Major Martin-Millar was born on the 12th Jan., 1867, joined the A.V.C. on the 26th Feb., 1896, promoted Captain 25th August, 1903, and Major on the 7th Dec., 1911. He was educated at Dublin University and the Royal Veterinary College, Camden Town, becoming a M.R.C.V.S. on 16th May, 1895, and a Fellow of the same College on 18th May, 1907. He served in 1902 in the South African war, receiving the Queen's medal with three clasps.

CHARLES WARD, M.R.C.V.S.,

Graduated, N. Edin: May, 1890.

Mr. Ward died on May 11th, at Church Stretton Salop, from cancer of the bowel. Aged 44 years. [Name removed from Register in 1902 under Sec. 5 (4) of the Act].

CORRESPONDENCE.

TREATMENT FOR SCLEROSTOMUM ARMATUM.

Sir,

Capt. Graham Rees-Mogg might try intravenous injections of atoxyl for the sclerostomes in his gelding. As a rule I have found the usual internal treatment effect a cure, but in a number of cases that have not responded to internal treatment, and became much emaciated, I have found atoxyl very effectual. Chief Veterinary Surgeon Brochberg, in an article reproduced in *The Veterinary Journal* some years ago, speaks highly of this agent. He says: "The 32 foals that recovered were treated with atoxyl with quick result, and all recovered, though very ill. After daily injections, living sclerostomes soon disappeared from the dung. The atoxyl was given partly intravenously and partly subcutaneously in large doses, increasing from 0.2 gm. to 0.5 gm. In individual patients up to 1 gm., and in one goat 1.5 gm. was reached. The commencing dose was:

R Atoxyl	} a.s. gm. 0.2.
Sod. Chlr pur	
Aq. dest.	

gm. 20.0.

I have not yet found the maximum safe dose, but have given three and four times the above amount to two and three-year-old Clydesdales for a week and ten days without toxic symptoms being shown.—Yours truly,

JOHN BROWN, F.R.C.V.S.

Invergordon.

THE MILK AND DAIRIES BILL.

Sir,

The text of the Milk and Dairies Bill at present before Parliament is now available, and as a measure closely affecting the future of our profession will repay careful study by those who care to obtain a copy.

The Bill is very far-reaching in general, and carefully administered should effect much. A particularly gratifying feature is the apparently common cause made by the two Government departments, the Board of Agriculture and Fisheries, and the Local Government Board, the existing position being most unsatisfactory for all concerned.

One or two clauses may require amendment, but my conclusions after hurriedly scanning the provisions of the measure are, that it will provide an enormous new field of work for veterinary surgeons, and generally speaking the Bill should receive the hearty support of our profession.—Yours faithfully,

J. W. BRITTLBANK.

Manchester.

NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

Sir,

In the report of the proceedings of the Royal Counties Association meeting printed in your last issue, a Mr. Toope, in advocating the formation of a Veterinary Inspectors' Branch of the Society, is reported to have stated that the National Association of Veterinary Inspectors was "practically *non est*," and that nothing appeared to have been done by them.

Judging by the consistency with which Mr. Toope has advocated "the formation of a Veterinary Inspectors' section of each Society throughout the South and East of England," without even mentioning the existence of the N.A.V.I., I am inclined to think that his obituary notice of the latter is a case in which the wish is father to the thought.

The expediency of forming a number of small sectional Societies of Inspectors, as opposed to an Association embracing the whole Kingdom, is apparently believed in by Mr. Toope, but I strongly object to his statement that the National Society has ceased to exist simply because he chooses to ignore it.

I freely admit that there are a few members of the Society who may have legitimate cause of complaint that their enquiries have not always received prompt answers, Mr. Toope, however, is not of their number, for he has never even replied to a most important communication addressed to him, affecting the interests of members—and he a Vice-president too.

Mr. Toope is perhaps not aware of the amount of work entailed in drawing up the schedule of suggested fees, circulating and tabulating the same, but it would be interesting to learn how he reconciles his statement that we "have done nothing," with the fact that the exact schedule as suggested by the Association has been adopted by the

majority of local authorities, the returns from which are available.

The utility of an Association such as ours, established for the purpose of furthering and protecting the interests of its members, cannot be assessed by the amount of material which is published. It was further never intended to hold frequent meetings owing to the National character of the Association, the objects of which would be entirely defeated by any hurried or insufficiently considered action, pending the time when experience of the working of the Tuberculosis Order points out to us the proper path to follow, alike in the interests of the public and ourselves. For months we have known that an amendment of the Tuberculosis Order was promised, and it is now imminent, and the new Milk and Dairies Bill is before Parliament. The latter is a most momentous measure so far as the interests of the profession are concerned, and particularly to those who are inspectors, or who will be appointed inspectors in the large field which will be opened up to us, and I submit that in a Kingdom-wide Association of Inspectors lies the machinery for securing the full measure of recognition which we deserve, rather than in the formation of small societies of inspectors such as Mr. Toope so fervently advocates. In this connection I would refer your readers to the letter of Mr. Percy Simpson, read at the Royal Counties meeting, the contents of which I fully endorse.

If there are any members of the Association, other than Mr. Toope, who consider that the Society has done nothing to justify its existence, I would ask them, in the meantime, to withhold their criticisms. Illness and family bereavement of two of its chief officials have largely interfered with the work, the value of which all members will now be in a position to estimate almost immediately.—Your obedient servant,

TREVOR F. SPENCER.

Hon. Sec., National Assn. of Vety. Inspectors.

Kettering. May 20.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1351.

MAY 30, 1914.

VOL. XXVI.

THE POSITION OF THE R.C.V.S.

Next Wednesday is not Derby Day, and the annual general meeting ought to be better attended than usual. Although the Council election is unexciting, there is ample material for discussion in the report. The projected Charter, the new regulations for the Fellowship Degree, and those for the Diploma in Veterinary State Medicine, will all be open to debate. All these attest the desire of the profession for progress, while the financial portion of the report shows how seriously that progress is threatened by poverty.

Few, perhaps even now realise how rapidly we are drifting towards bankruptcy. Our expenditure has exceeded our income for six years past. At first the deficits were not great, and we met them by an overdraft at the bank in preference to selling stock. We first sold £1000 worth of Consols in the latter part of 1911, but so much of the proceeds went to repay the bankers that another £1000 worth had to be sold about May, 1912—just two years ago. To-day we are again faced with a banker's overdraft of some £140, and a third sale of Consols is imminent. Further, this year's annual report states that the total excess of expenditure over income for the last six years is £2053 18s. 3d., and that over a quarter of that sum is accounted for by this year's deficit of £534 5s. 2d. This shows the rate at which we are moving. Probably we may expect another sale of Consols before the end of 1915, and after that they will become almost, if not quite, annual events.

Of course the passage of our Bill would put an end to all these money difficulties. But the Bill was first introduced to Parliament in 1911, and is now before the House for the fourth time. In previous years its chances of coming up for second reading have never been very good; and this year it has practically no chance at all. Given good fortune at the ballot, it may become law next year. On the other hand, under the present Parliamentary conditions, another four years or much more may elapse before it even obtains a hearing in the House—and not many years will bring us actually face to face with bankruptcy. It seems quite possible that, after all, the Council may soon be forced to ask for voluntary subscriptions—not, of course, as an alternative to the Bill, but simply to keep the College afloat until the Bill is passed.

FRACTURE OF ARTICULAR EXTREMITY OF SCAPULA.

I enclose two photographs of the articular extremity of the right scapula of an Artillery horse with the tuberosity knocked off and broken into three pieces, two of which had become joined by the usual method of healing. The junction between the two resulting pieces and the scapula was simply by cartilage: the tuberosity being considerably larger than normal though not appreciably so during life.

The remarkable thing about it is that the horse was in hospital for only 35 days in February—March, 1913, with it; the cause of lameness was then described and diagnosed as a sprain of the biceps muscles. Since 14th March, 1913, the horse has been regularly at work, and during the drill season of 1913-14 marched for practically three months, which included one practice camp. The horse was seen to be lame again at the annual casting; an arthritis of the shoulder joint (a thing rather common) being suspected, the animal was cast and destroyed.

C. E. STEEL, Capt., A.V.C.
Divisional Vety. Officer, 3rd (Lahore) Divn.,
and in charge Station Vety. Hospital.

ANTHRAX AND EMERGENCY SLAUGHTER.

A short time ago I received a message from the Abattoir that the carcass of a cow had been brought from a farm in a butcher's float and while being dressed in the slaughterhouse set apart for such cases, the meat inspector saw suspicious signs, and suspended further dressing until I had seen it.

On examination, I found that the bowels were filled with a bloody fluid, and in the mesenteric fat there was a hæmorrhagic patch about three inches in diameter. There were small hæmorrhagic patches in the peritoneal surface of the carcass.

The spleen was *normal* in size and consistency. The muscles had a parboiled appearance. The blood, which had dripped from the head, which had been cut off and hung up, was *coagulated*. I made smears from the spleen and hæmorrhage and found numerous bacilli which were Gram positive. I concluded it was a case of anthrax and reported to the Board of Agriculture, and the case was confirmed.

It seemed to me that this case was worthy of record because the two most important characteristics of an anthrax carcass, viz., enlargement of

spleen and character of blood, were absent, and as many animals are killed "to save their lives," it is just possible that amongst them there are cases like the above, which, although condemned as unfit for human food, are not dealt with as anthrax carcasses.

ERNEST J. BURNDRED, M.R.C.V.S., D.V.H.
Blackburn.

ABSTRACTS FROM FOREIGN JOURNALS

STUDIES UPON SWINE FEVER—THE SPIROCHÆTA SUIIS AND ITS CHARACTERISTICS AS A PATHOGENIC ORGANISM.

W. E. King and G. L. Hoffmann have published (*Journal of Infectious Diseases*, Chicago, 1913), an article upon this subject. The *Spirochaeta suis* is an organism which is found in the intestinal ulcers, the crypts of the cæcum, and the external local lesions in animals suffering from swine fever. It is a typical spirochaete, and in some of its characteristics it resembles some organisms whose nature and life histories are better known, such as the *Spirochaeta pallida*, the *Spirochaeta gallinarum* and others. The *Spirochaeta suis* seems to be able to disintegrate into granules, and these granules apparently form an important part of the life-cycle and physiological activity of the organism. They are contained in the blood of pigs suffering from swine fever, and in cultures of the *Spirochaeta suis*, and they are capable of causing the disease in healthy pigs.

In the blood of pigs suffering from swine fever, the presence in small numbers of a comparatively large spirochaetæ has been demonstrated. As this organism has not been found in healthy pigs it may represent the *Spirochaeta suis* in a transition form.

The *Spirochaeta suis* is an obligatory anaerobic organism, which requires an incubation period of some weeks before it grows on artificial media. It can be carried over from generation to generation on artificial media. When cultures which contain the organism in the form of both spirochaetæ and granules are passed through a Berkefeld filter, the spirochaetæ remain behind, while the small granules pass the filter and are able to cause swine fever or resistance against the disease.

The *Spirochaeta suis* produces typical swine fever in healthy pigs into which it is injected. This is the case not only with infective cultures which have been sown directly from the intestinal ulcers of swine fever patients; third or fourth generations upon artificial media which contain the *Spirochaeta suis*, and similarly the Berkefeld filtrate of the same agent, are able to cause swine fever and definite reactions which bespeak more or less protection against the disease. The pathogenicity of these cultures does not seem to be caused by the passage of an unknown "invisible micro-organism," which is finally transmitted to healthy pigs by the inoculation. Control experiments show that the

pathogenicity of cultures of the *Spirochaeta suis* belongs to this species itself in the form of spirochaetæ and granules.

Finally, in pigs which have been given the disease by cultures of the *Spirochaeta suis*, the organism has been demonstrated by dark-ground illumination in the intestinal or external lesions.

From the foregoing results, which have practically fulfilled Koch's postulates so far as this is possible with an organism possessing the biological properties of the spirochaete, it can be concluded that the *Spirochaeta suis* is better established as the specific cause of swine fever than any other known organism.—(*Berliner Tier. Woch.*)

W. R. C.

UNITED PROVINCES VETERINARY MEDICAL SOCIETY.

The third annual meeting was held on April the 11th and 12th at the Kaisar Bagh Baradari, Lucknow. 115 members were present, as well as many Zamindars who were interested in the proceedings.

Mr. E. W. OLIVER, I.C.V.D., in opening the meeting, congratulated the Society on its progress and work, and called attention to the great advances made in veterinary science during the last few years. He pointed out the responsibility which rested on the veterinary profession not only in the preservation of the animal wealth of India but also in connection with the public health of the community.

In enumerating the various diseases which are communicable from animals to mankind, Mr. Oliver remarked how little the public generally seemed to appreciate the part played by the veterinary surgeon of to-day in the interests of the community, and predicted that the time could not be far distant when the Government and the people must realise the usefulness and necessity for a strong and well equipped veterinary service.

Mr. WILSON, M.R.C.V.S., in a sympathetic speech, pointed out the encouragement which the Society's efforts and the scientific magazine had met with during the past two years.

SKEIKH NIAZ MOHAMED, Deputy Superintendent, C.V.D., after pointing out how necessary it is for scientific men to keep themselves up-to-date in their professional work, read a most interesting paper on "Piroplasmosis."

The following interesting papers were read and discussed:—

"The Economical Feeding of Cattle in India," by V. I. Tek Chand.

"Foot-and-Mouth Disease," by V. I. Imdad Hussain.

"John's Disease," and "Tuberculosis," by V. I. S. M. Raza Husain.

"Canine Distemper," and the "Use of Vaccine," by G. B. Roy.

Many interesting subjects were introduced by other members.

At the close of the discussion of more technical subjects, prizes and medals were awarded to members for valuable work, literary and otherwise, carried out through the year.

It was resolved that a magic lantern equipment and slides dealing with veterinary hygiene and sanitation be purchased from the Society's funds, with a view to giving demonstrations at horse and cattle fairs and in villages, and otherwise interesting the cultivator and animal owners in the subject of live stock.

It was decided that in view of the present fodder famine one hundred rupees should be forwarded from

the Society's humble resources to the famine fund towards the supply of fodder to the poorer owners of cattle in the province.

The services of Mr. S. C. Bhattacharjya as President of the Reception Committee, were very widely appreciated, and an Executive Committee was formed to conduct the work of the Society with Sheikh Niaz Mohamed, Deputy Superintendent as President and S. M. Raza Husain as Secretary.—*Indian Daily Telegraph*.

THE VETERINARY ASSOCIATION OF NEW SOUTH WALES.

The Annual Dinner was held at Paris House on Tuesday evening, the chair being occupied by Mr. S. T. D. Symons, Chief Inspector of Stock, and President of the Association. After the usual loyal toasts, Dr. S. J. Johnston proposed "The Veterinary Association," urging the members to push on with the proposed Veterinary Surgeons Bill, as he supposed the evils of quackery were as great in veterinary medicine as in human medicine.

The PRESIDENT, in replying, briefly outlined the history of the Association, and was able to show that the membership was steadily increasing, chiefly as a result of the graduation of students from the Sydney University Veterinary School, while the financial position of the Association was strong. As an instance of the way in which the Association was pushing forward the interests of the profession, and endeavouring to protect the stockowner from imposition and the stock from unnecessary suffering, Mr. Symons mentioned that the Association had been instrumental in bringing

about a discontinuance of the issue of certificates in veterinary science at educational establishments other than the University, as frequently such certificates, although gained after a very short and elementary course, were made use of by the holders in such a way as to induce the public to regard them as fully qualified veterinary surgeons. Again, the Association had been instrumental in obtaining the withdrawal of certain advertisements which were misleading and calculated to impose on the public. He concluded by expressing the hope that the Veterinary Surgeons Bill might soon become law.

Prof. DOUGLAS STEWART, in welcoming the visitors, noted how wide were the ramifications of the veterinary profession, as indicated by the guests present.

Mr. CHALLIS, Chief dairy expert, Union of S. Africa, replying, acknowledged the debt which he personally and those he represented owed to the veterinary profession in South Africa, as without its aid in the control and eradication of disease, dairying would have been practically impossible there. He spoke also of the benefit which he felt he had gained, and the knowledge he had acquired during his recent trip through Australia and New Zealand.

The health of Mr. C. J. Sanderson, who is about to proceed to England to purchase stock for the Department of Agriculture, was drunk with musical honours, and with toasts for the Army (replied to by Captain, Matson), the Secretary, and the Chairman, a highly successful function was brought to an end.

Amongst those present were: Dr. Kesteven, Major Melhuish, Dr. Dodd, Captain Callow, Messrs. Bell, Doyle, M'Masters, Veech, Hindmarsh, Oliver, Woods R. Stewart, Thorpe, J. M. Stewart, and Max Henry, Hon. Sec.—*Daily Telegraph* (Sydney), April 14.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, May 25, 1914
NOTE.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

MIDLAND COUNTIES
VETERINARY MEDICAL ASSOCIATION.
[NATIONAL V.M.A. NORTHERN BRANCH].

The quarterly meeting was held at the Grand Hotel, Birmingham, on Friday, May 15th. The President of the Association, Mr. J. Malcolm, of Birmingham, occupied the Chair, and other members present were: Messrs. M. Tailby, B. DeVine, L. C. Tipper, E. O'Neill, J. Young, S. Woodward, Birmingham; J. Martin, Wellington; W. G. Thompson, Stafford; R. Murray, Rugeley; A. B. Forsyth, Cannock; R. C. Trigger, Newcastle-under-Lyme; J. J. Burchnall, Loughborough; A. Over, R. Over, Rugby; W. L. Gascoyne, Lutterworth; W. E. Ison, Atherstone; H. L. Pemberton, Bridgnorth; E. Beddard, Wolverhampton; W. H. Brooke, Handsworth; J. A. Gold, Redditch; W. S. Carless, Worcester; T. Slipper, Sutton Coldfield; H. Collett, West Bromwich; L. W. Heelis, Solihull; W. Dale, Coventry; H. Yeomans, Smethwick; F. V. Steward, Hereford; C. F. Parsons, T. J. Brain, Cheltenham; F. B. O. Taylor, Stratford; R. L. C. Forrest, Alcester; D. Forwell, Towcester; and the Hon. Sec., Mr. H. J. Dawes, of West Bromwich.

The visitors present were: Prof. Mettam, Dublin; Councillor D. Rose, Chairman of the Stables Committee of the Birmingham Corporation; Messrs. J. Laithwood, Congleton; W. G. White, W. D. Connochie, Birmingham; and T. Thomson, Wolverhampton.

Apologies for unavoidable absence were received from Professors Sir John M'Fadyean, McCall, Macqueen, Hobday and Penberthy, Messrs. E. Ringer, J. Blake-way, Jun., C. M. Barton, F. L. Gooch, W. Blunson, W. H. Brown, C. E. Dayus, T. Ludlow, E. Franklin, R. Cockburn, C. W. Crofts, C. Haywood, W. F. H. Pickering, F. W. Barling, T. Hobson, R. B. Palmer, E. Hall, John Blakeway, J. Whyte, J. Martin, Jun., H. Thackeray, G. Thornton, H. S. Reynolds, J. Bainbridge, J. C. Deville, E. Woodcock, J. A. Connell, T. H. L. Duckworth, F. T. Prince, J. W. Coe, G. Wartnaby, G. Prickett, T. Chambers, and others.

THE PRESIDENT'S HOSPITALITY.

The company were entertained to luncheon by the President, at the conclusion of which his health was submitted in felicitous terms by Mr. Trigger. They were extremely fortunate, said Mr. Trigger, in having at the head of their Association during such an important year as this, a gentleman so highly honoured throughout the profession as Mr. Malcolm. The visit of the International Veterinary Congress to London was an event of great interest and importance, and in looking round for a President they chose one who will worthily represent this Association on such a memorable occasion. He wished Mr. Malcolm health and strength during what promised to be an eventful year of office.

The toast was drunk with much heartiness, and the President suitably acknowledged the compliment.

The minutes of the previous meeting were adopted.

New Members. Mr. T. THOMSON, of Wolverhampton, was nominated by Mr. W. G. Thompson.

Mr. F. O. TAYLOR, Stratford-on-Avon, was proposed by Mr. Gold, and seconded by Mr. Slipper.

Mr. R. B. PALMER, Warwick, by Mr. Gold, seconded by Mr. Martin.

Mr. F. E. HEATH, Moseley, Birmingham, by Mr. Tipper, seconded by the Hon. Sec.

These gentlemen, who had been nominated at the previous meeting, were elected.

THE HUNTING MEMORIAL FUND.

Mr. TRIGGER, in accordance with notice, moved the following resolution:—"That a sum of ten guineas be subscribed by this Association to the Hunting Me-

morial Fund." He remarked that everything was said that could be said at the last meeting on this subject. It was common ground that they ought to do all they could to perpetuate the memory of their old friend.

The resolution was seconded by the Hon. Sec., briefly supported by Mr. Gold, and carried unanimously.

THE LATE MR. GEORGE SMITH.

The HON. SEC. said that since their last meeting they had lost a very old and esteemed member of the Association in Mr. George Smith, of Tunstall. He was one of the most regular attenders they had, and it was always a pleasure to see him. His genial and kindly manner appealed to everyone, and they would miss him very much. He moved that a letter of sympathy be sent from the Association to the family.

Mr. CARLESS, in seconding, said Mr. Smith represented the old school of practitioners who, he was sorry to say, were fast dying out.

Mr. TRIGGER, as one practising in the same neighbourhood as Mr. Smith, begged to support the motion. He had known him ever since he commenced practice over forty years ago, and although they were rival practitioners their relations had always been of the most cordial description.

The motion was carried *sub silentio*.

COUNCIL'S REPORT.

The HON. SEC. presented the report of the Council of the Association:—

A meeting of the Council was held immediately prior to this meeting, when there were present: Messrs. Malcolm (in the chair), DeVine, Ison, Burchnall, Martin, Brooke, Slipper, R. Over, Pemberton Carless, Heelis, Trigger, Collett, and the Hon. Sec.

The following recommendations to the Association were made:—

That in view of the holding of the International Veterinary Congress in London in August, there be no ordinary meeting of this Association in August this year, but that to comply with the rules, which require four meetings annually, a formal meeting be held in London on one of the days of the International Congress.

That the November meeting of the Association be held in Nottingham, and that Prof. Gofton be asked to give a practical demonstration, the subject to be arranged by Prof. Gofton, the President, and Hon. Sec.

That the President and Hon. Sec. be appointed delegates to the International Veterinary Congress.

That no delegates be sent this year to the Royal Sanitary Congress.

The Hon. Sec. reported that the President and himself had signed, on behalf of the Association, a petition to the treasury for a pension for the children of the late Mr. Wm. Hunting, and he asked for an endorsement of that act.

The conjoint Veterinary Association of Ireland asked for support for their candidate (Mr. Howard, of Ennis) at the next election, and it was recommended that no combined action be taken, but that members could rest assured that Mr. Howard would make a good member of Council if elected."

Mr. TRIGGER moved the adoption of the report of the Council, and the President, in seconding, explained the reference to the petition for a pension for the children of the late Mr. Hunting. He said there was no time to be wasted, and as he knew what the feeling of the members would be in the matter, he and Mr. Dawes acted on their own initiative. They signed the petition themselves, and induced a few public men in Birmingham, such as the Lord Mayor, the Vice-Chancellor of the University and Mr. Jesse Collings, M.P. to do the same.

The report was then adopted.

PRESIDENTIAL ADDRESS.

Mr. JOHN MALCOLM, F.R.C.V.S., Birmingham.

Gentlemen,—You will expect me to follow the established custom of your presidents, and make a few remarks on some points of current interest on taking the chair at the first quarterly meeting of our Midland veterinary year.

On this occasion I feel sure you will desire me to be as brief as possible in order that you may have requisite time to hear Prof. Mettam's address on the important subject of foot-and-mouth disease, and to permit thereafter a full discussion on this subject.

In attempting to thank you for electing me your President for the year, I have to ask your indulgence. No words at my command can adequately express what I really would wish to say. The signal honour you have conferred upon me in order that I may once again represent your Association at an International Veterinary Conference is an appreciation which I am very conscious I have done far too little to deserve, but which I value very highly and the remembrance of which I shall always treasure. I am not naturally of an envious disposition, but to-day I am tempted to wish that I possessed a small measure of the gift of eloquence which some of my predecessors seemed so richly endowed with, so that I might have been able to convey to you in adequate terms my deep sense of your long and continuous personal kindness and professional confidence. As it is I can only ask you to accept the will for the deed.

Before saying anything on current topics I should like with your permission to be for a moment reminiscent.

The Midland is one of the older associations, and almost from the day of its foundation in 1866 it has been a leading provincial one. The Secretary tells me that during the first decade its members had some real difficulties to surmount, but, whatever their extent, they were quickly overcome for, in 1881, when I joined the Association on coming to Birmingham, it was in a very vigorous and flourishing state. As it was then so has it continued to be—an up-to-date practical veterinarians' association, not only dealing with our every-day affairs but taking an interest in pioneer professional work wherever displayed, and ever ready to put such work to the test of practical experiment. In thus sifting the wheat from the chaff it has been second to none.

From the papers read, the experiences recorded, and the demonstrations given, as well as from the excellent relationship maintained between members, this Association has provided a valuable meeting ground for all within its reach. Personally I know that my joining it has proved one of the best things I ever did. In no other way could I have obtained quite the same practical information, and in no other way could I have secured so naturally the needed professional fellowship or so freely the right hand of friendship wherever I went. This experience convinces me that those young Midland veterinary surgeons who have not yet joined would lose no time in doing so if they realised all that membership gives.

It is true that the Association is no longer the independent local entity it was prior to the general affiliation of the local societies with the National to form one federal whole. But I am confident the Midland has gained far more in possibilities for good from affiliation than it has lost. Though no longer isolated it is still essentially independent, and retains those midland characteristics of which we have been so justly proud and which have marked it from the beginning. That organised union is strength is a common-place fact of to-day; and we may now justifiably look to the National with its new federal strength to do far more for our

common good than was possible by the independent action of the societies in the past.

As the work of the National Officials must necessarily be greater in the future it will be necessary to take care that the right men are chosen from time to time to fill the responsible positions; also that our bye-laws are adequate to secure that no temporarily dominant section can run the Association to the possible detriment of the other sections.

The only change that one really regrets in our Midland Society is the change in the *personnel* through the loss of members. But this is a change inherent in all societies of any size and duration, it has been inevitably in operation from the beginning, for this Society claims no exception to the common law. We have now none of the founders of the Society with us, and our nearest link is that in one of our members we have the son of one of the founders. And I may here say that we look with no uncertain expectation to Mr. Ison to do his share as loyally and unmistakably in strengthening the Association as his father did in its early days. Of the 108 members and seven associates now on the list only six were there when I joined. I am afraid, therefore, I can no longer question that I am now one of the older members; as such I have joined with the other old members in mourning the loss of many colleagues. At the same time it has been a great boon to have known such personal friends and past pillars of the Association as Francis Blakeway, Harry Oliver, W. Carless, J. M. Parker and a host of others too numerous to mention.

Since our last meeting the decease of our old friend George Smith increases the list of those who have passed into the great unknown. In him we have to mourn the loss of one of the most loyal, upright and consistent of the early members. He was one whom we were all glad to know, and whom we all affectionately called George—no uncertain tribute to his personal good qualities.

Of those not now on the list but still happily here some have withdrawn probably for financial reasons, others to carve out their fortunes elsewhere. Of the latter none have obtained greater eminence than the one time Birmingham member, now the honoured Principal of the Dublin Veterinary College, whom we are again glad to see at one of our meetings.

Among the half dozen present members who were on the list when I joined, there is one who has done exceptional work for the Association on the Council, and among those who joined soon after there is another who has done yeoman service as Secretary. It is some gratification to me to think that I showed what time has proved to be wise prescience in the interests of the Association when a quarter of a century ago I proposed the nomination of Mr. Trigger as our representative for Council, also when two years later I nominated Mr. Dawes as secretary. No society could have been better served in either capacity, and your endorsement of these nominations ever since shows how thoroughly you have recognised this.

One and all will agree that there is nothing to record but what is satisfactory respecting the Association; but it is otherwise with regard to the individual members. In many cases their recent experiences and their prospects are unsatisfactory. In the Midlands as elsewhere, modern exigencies and the spirit of the age are in certain directions against the veterinarian. The motor has already hit many practitioners very hard, and that in the best paid and most pleasurable part of their practice—the horse practice. And so far as one can see at present the landslide in horse-practice is likely to continue and to overwhelm many who have specialised in this line unless they turn their attention to other fields in the future. Fortunately, there are certain fields open to attention, though probably these

will prove less remunerative and less congenial than that of equine practice.

In the Government Service at home, in India, and in the Colonies the demand for capable young veterinary surgeons has shown a wonderful expansion, and is still increasing. Similarly, in our Municipal and other local public services the openings in connection with meat inspection, dairy inspection, contagious diseases and public health preventive medicine generally, also show an encouraging increase. In connection with tuberculosis and other Board of Agriculture work, it is a pleasure to record that the Board in its recent enactments requires that work that is essentially veterinary in nature shall be carried out only by veterinary surgeons, and there are indications that other Government departments are likely in the near future to follow similar lines. It now lies with us individually and collectively to see that these indications become realisations. We have recently seen that if a sufficient body of the public require that any public veterinary work should be done by veterinarians the Government will acquiesce and legislate accordingly. What we therefore require to do is to educate the public in the right way and as to what is really our work. Individually our clients recognise that we alone are equipped for any specific veterinary public work. When we can induce them collectively to require our services for such work our battle will be won. In this educational crusade we need the help not only of the Royal College of Veterinary Surgeons and the Veterinary Associations, but in particular that of every individual member. In mentioning these indications of new openings to our members we do not forget that the mainstay of the profession, general country practice, as well as the Army, requires as many men as formerly.

If my time and your patience had permitted I should have liked to take advantage of the present opportunity and speak on several matters that interest me, and may also be of interest to you, but as neither time nor patience allows I shall not trespass on your indulgence further than to make the briefest passing reference to one or two of these, such as the delay in eradicating glanders, the easy diagnosis of mange, the rapid diagnosis of contagious abortion, the prevalence of John's disease, the failure to eradicate swine fever, and one or two points respecting tuberculosis and dairy inspection.

THE DELAY IN ERADICATING GLANDERS.

One cannot help marvelling at the number of years required to eradicate glanders in the London area. There can be no justification for this delay. We know that the present powers, if efficiently and uniformly applied, would have cleared greater London years ago, as they have other localities. We acknowledge the London veterinary inspectors' competency, and we are sure they are not responsible for the result. We can only conclude that there has been some factor at work not evident to outsiders and which has cost the London ratepayers ten times the amount that was necessary to eliminate the disease. It is unnecessary to say to veterinary surgeons that if all the infected horses in London were killed to-day the cost of eradication would at once cease. One naturally asks why London alone has failed to find the infected. I remember when the present Glanders Order came into force, and I had 30 horses killed on one day, my chairman was aghast at the cost, but when I explained the effect of keeping infected horses alive I received his most hearty support, and in three months Birmingham was free from glanders and we have only had to deal with isolated introductions since. We and others continue liable to such introductions as long as London remains infected, and that is my excuse for mentioning this subject to-day.

THE EASY DIAGNOSIS OF PSOROPTIC MANGE.

Some members seem to experience a difficulty in finding the acarus in mange cases. In treated cases there is often a difficulty. In untreated ones it is a simple matter. If the scales from the circumference of an affected patch of skin are spread out on a pane of glass and the glass is gently heated over a gas flame the living acari commence immediately to run about, and they are then easily seen by a naked eye or through any hand magnifying glass. I feel I owe you an apology for mentioning this old simple method here, but for the recent remarks of two members I would not have dreamt of doing so. I have here an ordinary microscopic slide on which there are some 500 acari placed there on Monday last by Mr. Connachie. He will show you them under the microscope and you can count them if you like. He simply picked up the moving acari from among the dry scales on the glass plate with a needle whose point had been dipped in oil and the oil then lightly wiped off. The acari adhere to such a point and can be transferred with ease and rapidity from the glass pane to a drop of water, oil, or other liquid on a slide.

THE RAPID DIAGNOSIS OF CONTAGIOUS ABORTION IN CATTLE.

The work of Sir John M'Fadyean and Sir Stewart Stockman has made the laboratory diagnosis of bovine contagious abortion by the agglutination test such an easy, quick, and accurate method of diagnosis that no veterinary surgeon can be excused who fails to recommend his clients owning infected herds to have the blood of each animal submitted to the test. The result will enable anyone to separate the infected from the free with accuracy.

In submitting the blood no animal should be omitted, for bulls and virgin heifers may be infected as well as cows. In the future it should be a much less formidable and less costly affair to successfully deal with an infected herd than in the past. The disease has been of particular interest to me, owing to the difficulty experienced in attempting to eradicate tuberculosis and contagious abortion from the same herd. Even this may now be successfully tackled.

THE PREVALENCE OF JOHN'S DISEASE.

Our Birmingham abattoir statistics show that nearly as many carcasses are condemned from John's disease as from tuberculosis. Clearly John's must be much more prevalent than is generally supposed, and as it has hitherto resisted all treatment the loss sustained must be very considerable. In the past one has always advised that an animal affected with John's should be killed immediately, as cases always get worse, and the longer the affected are kept alive the greater the liability for their carcasses to be condemned. The record, in the current issue of the *Journal of Comparative Pathology and Therapeutics*, of a case cured under ferrous sulphate and sulphuric acid treatment is of more than passing interest. Anyone who introduces a real remedy for this hitherto invariably fatal disease must be regarded by farmers as a public benefactor. And the fact that one undoubted case has recovered should be a great incentive to fresh trials. It seems to me this is a matter well worth the Board of Agriculture's attention.

THE FAILURE TO ERADICATE SWINE FEVER.

The published statistics of the Board of Agriculture clearly show that swine fever has experienced no real decrease in recent years. The existing regulations have manifestly failed in their object to eradicate the disease in the past, and there are no good grounds for

supposing they will be more successful in the future. No one need wonder, therefore, at the discontent of pig owners and pig dealers, or at their derisive criticism of the Board's procedure, or, for that matter, at their lauding the serum or any other treatment.

Under the circumstances may we not now very naturally ask whether these unsatisfactory results are the best that can be expected in the suppression of swine fever? Must it be accepted that this disease is ineradicable by ordinary measures? Can nothing less than powers similar to those necessary to stamp out cattle plague be effective? And seeing that cattle plague measures have been ruled out of court here, must we be prepared to regard the continued prevalence of swine fever as inevitable, or may we still legitimately look for success by other and less drastic means? Notwithstanding past failure, the late Sir George Brown's memorable prediction, and the pessimistic views generally prevalent, I am one of those who implicitly believe in the possibility of eradication—and that without resort to cattle plague measures and simply by the introduction and application of a reasonable practicable procedure, less irritating, less open to criticism, and no more drastic in practice, than that which has so signally failed. Past experience has shown that eradication can be, and has been, temporarily effected sectionally. In fact the disease is continually being stamped out in small areas. Unfortunately, it is soon again introduced by importation from untraced sources of infection in other areas. What is now required is eradication in larger areas coupled with an effective system preventing re-infection.

We know that swine fever does not arise spontaneously. It has never been seen on a farm previously free unless and until introduced from outside. Each case arises directly or indirectly from a pre-existing one, though the latter frequently seems untraceable and remains untraced. It is the unsuspected infected pig, pig pen, pig excretions, pig offal and other pig products or other infected media, that are mainly responsible for the continued prevalence of the disease, and that require to be detected and the infection suppressed.

With respect to swine fever products from butchers' shops and restaurants, we know that many infected pigs pass the butcher without the disease being detected, and we believe infected offal and other products not infrequently pass back among pigs in the shape of food or manure. I have frequently seen cases of infected pigs in consignments sent to our market to be sold for slaughter, but before detection part of the consignments have passed through the market and been sent away to factories and shops outside our area. In such cases the outside local authorities have invariably been notified that these pigs were part of an infected consignment. I have systematically inspected the returns of swine fever to see whether the disease had been declared in any of these cases, and I have to confess I have never observed any declared case under these circumstances. Such undeclared cases are without doubt liable to be sources of infection, but to trace the effects is very difficult.

Needless to say the tracing and discovery of undisclosed cases is work for up-to-date expert veterinarians with practical experience of swine fever. Many such are in the service of the Board, and only such are fully competent to undertake the work. With our more accurate knowledge of the nature of the disease, our increased powers of differential diagnosis, and our fuller appreciation of the means by which infection may be spread, much better results should be possible in the future than have been in the past. But if this is to be secured it will necessitate a change in the Board's policy of central administration with its apparent lack of personal responsibility for results, and the substitution of an appropriate measure of decentralised adminis-

tration embodying the essential principle of individual responsibility within prescribed districts. If this were inaugurated the conditions which make for success would at once be immeasurably advanced. I do not suggest that there should be any loss of effective control by the central authority, nor necessarily any additional control by the local authority, though local official knowledge should be assiduously sought for and made use of. What I do suggest is that the country should be sub-divided into a number of districts, administrative districts, whose extent in each case should be governed by geographical position, the pig population, and the prevalence of the disease; and that experienced veterinary superintendents responsible to the Chief Veterinary Officer of the Board should be put in charge. Each superintendent would, of course, have to possess, or have soon to acquire, full personal local knowledge of his district, have to know what he had to overcome and how to overcome it, be empowered to apply and enforce all necessary regulations, whether they be slaughter, or segregation, or serum treatment, or other measure; be prepared to accept responsibility for results and be entitled to recognition for success. Movement within the district should be permitted except in infected areas, but no movement from outside districts should be permitted into a district except for slaughter where systematic post-mortems, would be carried out, or for breeding purposes under special regulations as to inspection before removal and inspection with an adequate period of quarantine after admission. In due course, when adjoining districts had been freed from the disease and had remained free for an adequate period, free inter-movement within these districts could be permitted, and with the continued elimination of the disease the procedure could be extended until in time the whole country became free.

There are certain large outlying districts whose geographical position and experience of swine fever specially lend themselves to such a procedure as I have suggested and where it could readily and inexpensively be put in operation and the effects observed. If this were done, and the right men put in charge, the results I am confident would soon warrant a general extension of the procedure.

RESPECTING TUBERCULOSIS AND DAIRY INSPECTION.

Percentage of Tuberculous Cows in Dairy Herds. During the seven years ended December 31st, 1913, we tested with tuberculin 2,955 cows for the first time. Of these 872 cows reacted or 29 per cent., shown as follows:—

Year.	Tested.	Reacted.	Per cent.
1907	51	22	43.1
1908	378	168	44.4
1909	421	128	30.4
1910	562	105	18.7
1911	429	124	29
1912	504	127	25.2
1913	610	198	32.4
	2955	872	29.5 Average

At the minimum end of the list of the herds tested, one herd of 14 cows was entirely free, one herd of 13 cows had one reactor, and one herd of 19 cows had 2 reactors.

At the maximum end of the list one herd of 45 cows had 37 reactors = 82.2%, and one herd of 52 cows had 30 reactors = 57.7%.

Percentage of Cows giving Tuberculous Milk. Our statistics show that of the cows supplying milk to Birmingham 1% of those outside and 1% of those in the city area are giving tubercle-infected milk. This is arrived at from the following: 7.5% of the milk churns coming to Birmingham contain tubercle infection, and

each churn contains approximately the milk of 10 cows. If each infected churn were infected only by the milk of one cow as it generally is, 75% of the outside cows supplying Birmingham would be giving infected milk. But occasionally there is more than one infected milk in a churn; e.g., the last infected churn we had to deal with contained three infected milks from a farm in Derbyshire. We reported the three cows and they were slaughtered by the County Council. It is rare to find infected milk from three cows in the same churn, but it is not so rare to find it from two. Bearing this in mind we can fairly assume that at least 1% of the outside cows are giving tubercle infection in their milk.

In comparison with this we have to record that of the approximate 4,000 cows within the City of Birmingham during the year, and subjected to monthly veterinary inspection, only four cows—1 per cent. were found giving infected milk. The difference is no doubt partly due to our systematic inspection, and partly to the fact that in most cases only good milch cows are purchased, and are sold again within the year.

Every Reactor an Infecting Cow. My colleagues unanimously agree with me that practically all reacting cows are, in a sense, cases of open tuberculosis, inasmuch as such cows are capable of infecting tubercle free susceptible cattle. When a cow recently infected but not yet a reactor passes the test and is admitted to tubercle free herd it will infect its most susceptible companions on its becoming a reactor—if not before. At one time or another we have heard much about Ostertag's method of stamping out tuberculosis by casting the clinical or open cases. In our practice there appears to be no closed cases in reacting cattle. Anyone who has a tubercle free herd and keeps it up by outside purchase of non-reacting cows will do well to retest every purchase within three months. If he does not, and a recently infected one happens to pass and is admitted to the herd, he will find in six months that not only the recent purchase but several others will have become reactors.

Reactors ceasing to react. We all know that if a cow is tested with tuberculin and reacts, and is again tested soon afterwards, it may then pass the test. Recently we heard of a man who boasted he was able to make any reactor pass, and we were informed of his method of procedure. We have recently treated six cows on his lines, one of these we tested a fortnight afterwards and one each week subsequently until all had been done. None showed any reaction. We purpose retesting them in another three months time to see whether they continue to be non-responsive.

Clean versus Dirty Milk. At the present time there is a great cry out about dirty milk and it has to be admitted that much of the milk on sale is disgustingly contaminated with dung, etc. A special effort is being made to remedy this evil and to supply clean milk. To aid this we require better constructed cowsheds and cleaner and better instructed attendants. It is not generally realised that the internal construction of the cowshed plays such an important part in the cleanliness of the cows, and consequently of the milk, as it does. A general defect in sheds with a feeding passage is the defective head partition. In most cases this partition is so constructed that the cows can either get their through or over it into the feeding passage. Cows when in this position drop their dung on the end of the cowbed and subsequently lie in it. To prevent this the partition should not permit the cow's head to pass through or beyond it. For a similar reason the managers should not be more than two feet wide and its bottom should be two inches higher than the level of the cowbed. To enable the cow to lie against the manger with her head over it, the height of the manger should not exceed 10 inches. High mangers tend to force the cows back into the gutter when they lie down.

The length of the cowbed should not exceed 5 ft. 6 in., and the width of the double standing 7 ft.; if they do the cow's dung will fall on the bed instead of into the gutter. The gutter should be not less than 6 in. deep at heelstone, 2 ft. 6 in. wide, have a fall away from the heelstone of 1½ inches and a fall of 1 to 30 lengthways. Such a gutter affords plenty of room for the dung and permits the rapid draining away of urine. The heelstone should be right angled. A rounded heelstone induces slipping. The milking passage, or passage behind the gutter, should be at least 4 ft. wide, and so prevent the splashing of dung on the back wall.

It is desirable that something like uniform specifications for the internal construction of sheds should be issued by the Local Government Board, and these should be drawn up after consultation with experienced inspectors. Whether this is done or not, it is essential that the inspection of cowsheds should only be entrusted to practical qualified inspectors who have had experience of the work, and who therefore know the best conditions for obtaining clean milk.

The cleanest milk I have seen was obtained from cows milked into special cans, in special dust-free milking sheds, where the sheds and cows were washed and the milkers' hands washed before the cows were milked. The difference in the bacterial count of such milk and the milk usually supplied is remarkable. One would naturally think that where a milking machine is used the milk would be very clean, but as a matter of fact the bacterial count of such milk is generally higher than where the milking is done by hand. This appears to be due to the practical difficulty in thoroughly sterilizing the various parts of a milking machine. I have here one of the special milking cans I have referred to. You will see it is so constructed that no dust present in the air or upon the cow can fall into the milk.

Gentlemen, I feel I owe you an apology for introducing so much irrelevant matter into a presidential address, and for having so long stood in the way of Prof. Mettam, who I know you are now impatiently anxious to hear.

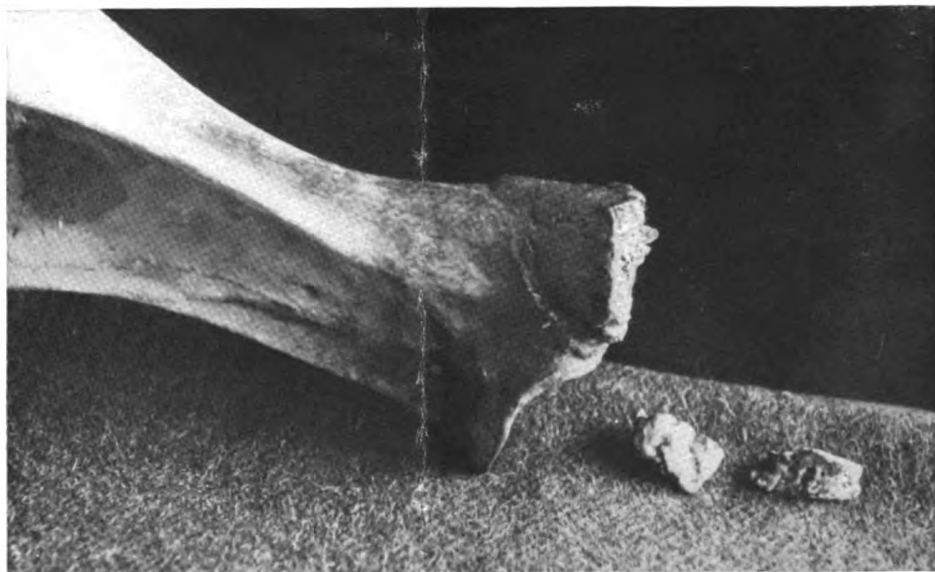

A vote of thanks to the President for his address, with a request that he would allow it to be published in the report of the meeting, was moved by Mr. Martin, seconded by the Hon. Sec., and carried unanimously.

FOOT-AND-MOUTH DISEASE.

By A. E. METTAM, B.Sc., M.R.C.V.S.

Principal, Royal Veterinary College of Ireland, Dublin.

From time to time foot-and-mouth disease appears in Great Britain, and during the last three years, in 1912 and the present year, the disease has also occurred in Ireland. How it is that for many months, or even as in the case of Ireland for many years, the disease is absent and then suddenly occurs without warning and without any clue as to its origin, is one of the perplexing problems of epizootiology. Occasionally isolated outbreaks occur which the most persistent inquiries fail to unravel, and in places where there has been no intercourse or connection with diseased centres and where no cattle have been introduced from other parts. Further, isolated outbreaks occur in places far removed from each other, occurring simultaneously or in quick succession, where there has been no direct or indirect communication between the infected centres, and where investigation has entirely failed to explain how the infection arose or whence it came. It would be relatively easy to explain the relative occurrence of the disease if infected animals were allowed to live, but so far as we know, all infected and in-contact animals are destroyed and the infection is wiped out from a centre where the disease is known to exist. It may be presumed

FRACTURE OF ARTICULAR EXTREMITY OF SCAPULA.

Illustrating note by Capt. C. E. STEEL, A.V.C.

MEMBERS OF THE UNITED PROVINCES VETERINARY MEDICAL SOCIETY
At the meeting at Lucknow, April 11th, 1914.

that once an outbreak is discovered and dealt with by the authorities that the infection for the time being has ceased to exist and that the country is free from the disease. If this be the case—and we are not asking too much to believe it to be so, since in many instances months may elapse before another case is reported and then only in some far distant part of the country—where does the infection come from? How is it spread? What means can we take to prevent the infection coming in? These are all questions which we of the profession are constantly asking ourselves. In cases of in-contact animals there is no difficulty in answering questions as to how animals previously healthy become infected. It is those outbreaks which occur singly with no previous history of contact with infection, which claim our attention and demand explanation.

Foot-and-mouth disease is a specific eruptive fever affecting cattle, sheep, and swine. It may occur and has been described in the horse; it is said also to occur in dogs, cats, and poultry. Man is also liable to infection. The cause of foot-and-mouth disease is ultra-microscopic, capable of passing through a bacterial filter. Whatever its nature, it has never been seen, nor has it been grown on artificial media in the laboratory. The virus is present in the fluid of the vesicles which develop on certain parts of the body, and so potent is the virus that it is said that 1-5000th part of a c.c., or '003 of a minim of the fluid of the vesicle is capable, in a susceptible animal, of causing infection. The amount of actual virus able to produce infection is much less than the quantities just mentioned because the virus is greatly diluted by the fluid of the vesicle. Infection may be caused by rubbing the virus upon the mucous membrane of the mouth, or by injecting the virus into the blood stream, deep into the muscles, or into the peritoneum. Subcutaneous injection of virus is an uncertain method of producing infection. Infection may also be set up by giving the virus in food or bolus. Young animals suckled by infected dams are infected by the alimentary tract, and most cases in man have occurred through infection by the alimentary tract. Infection may also occur through the genital passages, but for all practical purposes, save under experimental conditions, we may consider infection to occur through the alimentary tract.

Following infection, the incubative period varies from three to six days—lesions may develop earlier than three days in the pig—it may be deferred beyond six days. Very virulent virus is likely to have a short incubative period; somewhat attenuated or modified virus a longer incubation. During incubation there is a moderate amount of fever, but the temperature usually is not very high, and if there are no complications it rapidly falls again when the eruption of the vesicles has occurred. During the incubative period, and for a day or two afterwards, the virus is in the blood, but it soon disappears from the blood, which becomes non-infective.

The lesions occur in well defined regions in or about the mouth, on the skin of the heels, interdigital space and of the coronets; and upon the udder. They may be found also upon the skin of the genital organs, of the perineum, in the vulva, at the base of the horn, etc. The typical lesion is a vesicle or bleb developing in the deepest stratum of the cells of the stratified and squamous epithelium of mucous membrane or of epidermis. An outpouring of lymph from the vessels of the corium accumulates between the cells of the rete Malpighi, which are pushed apart and eventually disconnected. Many of them swell up and burst, or become liquefied. The accumulating fluid dissects up the rete Malpighi and raises the superjacent cells of the epithelium. These cells are more tough and resistant than the cells of the deeper layers, and do not so readily give way. The result is a pocket or cavity filled with fluid in the

epithelium, nearer the corium than the free surface. From movements of the animal, from some attrition, or even from pressure of the contained fluid or solution of the cells, the cellular membrane bounding the cavity of vesicle gives way and the vesicle ruptures. The epidermis may be shed or may curl up, or it may be merely fractured or ruptured, but the contents of the vesicle escape and active virus is liberated. The question may be asked here, Is the virus present in the saliva before lesions develop? Recent investigations have shown peculiar bodies in the salivary glands, which are believed by the discoverer to be the actual organisms producing the infection. There is nothing extraordinary in the question, Is the virus in the saliva before eruption of lesions? because such has been proved to be the case in rabies. The corium beneath the vesicle is exposed, save for a delicate covering of epithelial cells, or the only cells left are certain colonies in the depressions between the papillæ of the corium. The corium is highly congested, the vessels are filled with blood, the tissues appear raw, and if roughly handled readily bleed. The vesicles vary in size, but they may be half the size of a hen's egg in the bovine, or even larger, and after rupture a large area of corium may be quite, or apparently, denuded of epithelium. In the mouth the lesions are usually found on the tongue, inside the lips extending to the gums, or the dental pad of the palate. Lesions may be present in the fauces extending into the pharynx. Vesicles may be found on the muzzle and on the lips. In swine and sheep lesions, though they occur in the mouth, are not common in this situation. They are more common in the swine on the snout and upon the lips. In sheep they also occur on the lips. After the vesicles have ruptured the lesions soon heal, unless secondary infection should occur. In a day or two the more or less exposed corium is covered with a new layer of epithelium, this new epithelium being derived from the epithelium at the periphery of the lesion, and especially from the epithelium still persisting in the recesses of the exposed corium. The rapidity with which the lesion is covered with epithelium is remarkable, and it could never take place in the time if the new covering depended upon the epithelium at the periphery. In sections made of the epithelium covering vesicles in the mouth it is not rare to find numbers of large granular corpuscles which may even be present in the interstices between the epithelial cells, interstices which have been greatly widened by the infiltrating lymph. Some have considered these corpuscles as the cause of foot-and-mouth disease, but they are only the familiar coarsely granular eosinophilous corpuscles which have been attracted to the part. Similarly from their presence near the lesion, and reasoning from analogy, which is not always safe, it has been surmised that the undiscovered virus of foot-and-mouth disease is probably an animal parasite.

Animals that have recovered from an attack of foot-and-mouth disease possess an immunity to a varying degree. How long this immunity lasts is very doubtful. Some claim it may persist for months, or even years, whilst there are others who declare that the same animal may show signs of infection several times in a single year. Cases are also recorded of animals being infected a second time shortly after having recovered from the first attack. It appears to me that if an immunity be established—and there is no reason to doubt that some degree is set up—then, if the immunity breaks down, it breaks down in the presence of a strong virus, probably a virus of stronger virulence than that causing the primary infection. There appears to be every reason to believe that the virus of foot-and-mouth disease varies in its virulency just as in swine fever, horse-sickness, diseases also due to ultra-microscopic viruses, the virulence of the virus varies in different outbreaks or in different districts. Animals immunised against a parti-

cular strain of virus may not be able to resist inoculation, or exposure to another and apparently more potent virus, and so an animal which has recovered from foot-and-mouth disease may, though it possesses an immunity against the virus producing the primary infection, altogether fail to resist infection by a second virus. That the virus of foot-and-mouth disease is variable as to its virulence there is no doubt. The fact is thoroughly well-known that, among well grown cattle, the severity of attack as gauged by mortality varies. Somewhat similar facts have been noticed in India. Not only is great difficulty experienced in setting up the disease by inoculation, but when the infection is produced its course is that of a mild infection, and the infection tends to rapidly die out. Animals in India, where the disease has been known from time immemorial, possess relatively and actually high immunity against the infection, and doses of lymph five hundred times as large as that which would cause infection in an ox at home may fail entirely to infect the puny, delicate-looking native Indian cattle. Generally, complications excluded, the mortality is slight, save among young animals at the teat, which may develop intestinal lesions and die. In some outbreaks the mortality, even among grown stock, is high, as witness the Barcelona outbreak in 1901, when the percentage of death rose to 70 and over, so much so that it was feared that rinderpest was present. So I think we are justified in concluding that the virus varies in its potency, and such being the case an immunity to one strain of virus may quite break down before another virus.

On the Continent, where they have a greater experience of foot-and-mouth disease than we have, and where outbreaks are not treated so drastically as we find necessary, members of the profession not only treat the cases, but have opportunities of keeping their patients under observation. It is reported that cases occur where the animals die with what is called the apoplectic form of foot-and-mouth disease. In Italy two forms are recognised, according as to whether the animal is young or an adult. In the young the symptoms occur on the earliest sign of infection; in adults during convalescence, when they begin to feed and the milk secretion returns. The animals die suddenly when feeding or drinking, or when being milked, without any previous warning. Sometimes there is dyspnoea, muscular tremors, a tottering gait, grinding of the teeth, and death occurs from syncope without convulsions. In other cases the animals are in a state of complete paralysis.

At the post-mortem examination the constant lesions noticed are referable to the heart. The heart is flaccid, has stopped in diastole; the coronary furrows contain much serum, i.e., the tissues are infiltrated with an oedematous fluid. The heart also shows fatty degeneration, and there is also parenchymatous and interstitial myocarditis. The conditions here observed have been repeatedly noticed by others, even as long ago as 1884 by Johnes, and were especially studied by Kitt. In addition to these heart lesions, lesions may be found in the intestines and especially of those animals dying on the fifth or sixth day of infection with apoplectic symptoms. In the intestines there is a catarrhal and hæmorrhagic enteritis. In most animals examined there is hyperæmia of the central nervous system; the vessels are dilated and filled with blood; there is perivascular infiltration; changes occur also in the nerve cells. All the lesions described are those associated with the action of toxin or a very virulent virus. The cause of death in these cases is usually assigned as due to heart failure, the consequence of the action of the toxin.

Immunity, we may assume, is established to some degree after recovery from an attack of the disease, and animals may be immunised experimentally by inoculation of hyper-immunised serum, or briefly anti-serum, or by a mixture of serum and virus. The immunity

given by the injection of an anti-serum is passive and temporary; that given by the injection of virulent lymph is active but variable. In this country experimental work with foot-and-mouth is not possible; so long as foot-and-mouth virus is in the country there is an infective centre. No matter how careful one may be, there is always the risk of the virus getting out of control, out of the laboratory, and the infection occurring in cattle beyond the laboratory. At least, that is the experience of other countries. We have, therefore, to fall back upon the experimental work done in Germany by Prof. Loeffler and others, and in France by the late Prof. Nocard, Leclainche, Vallée, Moussu, Carrée, and others. The general findings amount to this, that it is possible to prepare an anti-serum; that the anti-serum in large doses is capable of setting up a temporary immunity. The temporary immunity may be strengthened by inoculating protected animals with lymph (old, attenuated or fresh lymph heated and mixed with old lymph, etc.), but the method is costly and risky; costly, because it is necessary to have always at hand a supply of suitable virus or lymph; risky, because of the danger of the experimental station being an infective centre to the country around. So far as I can ascertain, there is no really reliable serum to be obtained, and its only value—and a hypothetical one at that—is that when given in large doses it may protect animals against possible infection, such as, for instance, might occur at an agricultural show.

The injection of virulent lymph even when used in conjunction with an immune serum may be followed by eruption of vesicles. The course of the infection may be modified by the use of the serum, but, as the lesions develop, virulent material is present ready to produce infection if suitable subjects are at hand. The use of virulent lymph combined with immune serum is not a practical method of creating immunity in the field. Serum has been obtained from both cattle and horses after hyper-immunisation. The horse provides immune serum more rapidly than the ox, and its serum is more suitable for the pig and sheep, though not so good for use with bovines. The lymph for use in immunising experiments is provided by swine, which, after developing the lesions from which the lymph is recovered are injected with immune serum.

Another point of importance, showing the impracticability of the use of serum, is that if the serum is able to give protection to the animal injected for a few weeks it is necessary to make repeated injections at intervals to give anything like an immunity or protection lasting twelve months. No method of immunisation is likely to commend itself to professional man and layman alike unless a simple injection with minimum risk is followed by an immunity of some months duration.

Vitality of the Virus. If one has the virus in hand there is no great difficulty in destroying it. A comparatively low temperature is fatal to it, and it cannot withstand the action of even mild disinfectants. Probably it is soon destroyed by sunlight and exposure. It used to be thought that it could not persist long outside the body, and that in a month or two it lost its infectivity and became innocuous. There are good reasons, however, to question this opinion. Prof. Bang has furnished evidence of outbreaks occurring on farms where it was impossible to exclude contaminated fodder in which the infective agent had remained for 12 months. Outbreaks occurred at intervals of 12 months. Incidentally, these outbreaks mentioned by Prof. Bang show that immunity may last for more than 12 months, even two years, because the animals first attacked were allowed to live and they were not infected at the second outbreak. It is possible for virus to reach hay and straw from the boots and clothing of those in contact with diseased animals and that when the hay and straw are used they convey infection. There is little doubt

but that hay and straw infected in the way described do account for the reappearance of the infection upon certain farms.

In Fleming's Veterinary Science and Police is an account of cattle imported to Australia from Britain developing foot-and-mouth disease when nearing their destination and hay being the vehicle of the infecting agent. I am loth to disturb old stories, but perhaps this has served its time and generation. I will, however, improve upon it by giving the truth. My information is from a reliable source and is first hand. The cattle were exported to Australia, being carried in a sailing boat which reached Sydney Harbour 89 days after clearing the Thames. Every precaution had been taken to guard against foot-and-mouth infection, and the fodder was obtained from sources where infection was unknown. If foot-and-mouth disease was due to the fodder, the fodder was infected on board ship. Daily from the time the ship left the Thames until the disease broke out the captain entered into a log his opinion of the cattle's condition. When the boat was nearing Sydney foot-and-mouth disease developed. Here is the explanation. The importer of the cattle sent his own man from Australia to bring the cattle home, and this man, according to the testimony of a sailor who assisted him, when the ship was three days out of Sydney, brought up from the hold a parcel of sheep skins which he had purchased in London. The sailor helped him to put up these skins about the animals to form a screen, that the importer might be impressed with the thoughtful care of his man for the animals he was conveying. The animals became infected either directly from contact with the skins or from contamination of fodder or other food or drink from the skins. There seems to be little doubt that the skins brought in the infection. Incidentally the story supports the contention that the virus may remain potent for a longer time than is generally believed.

I do not think there is much doubt that infection may be introduced by contaminated food stuffs. I see no reason to deny that hay and straw, green food, corn, even milled grain and the usual derivatives, may be contaminated and cause infection when used as food. There are so many things imported nowadays from places abroad where the disease is rife that it is almost impossible to exclude anything as a possible carrier. I am also of opinion that straw and hay used as packing material are dangerous. In certain places large quantities of goods are imported packed in straw and hay, and such may come from contaminated places. At least it is wise in these islands to consider the stuffs possibly infective. I know, for instance, of one case where the packing material, apparently good clean straw, amounts to two waggon loads a week. Despite that it appears uneconomical, that particular straw is burnt rather than any risk should be run. Look at the amount of the stuff coming daily into the United Kingdom from abroad. Not only manufactured goods but also raw material, which may come into contact with food used upon the farm. Railway waggons are not always cleansed as they should be, and when a truck is hired to convey a load the hirer does not know what the truck had just carried. As an instance, I heard once of a load of grains or brewer's draff containing among other things a cow's ear. Apparently the truck had just before been loaded with hides. I don't know if the hides were home or foreign, but the instance shows me the enormous possibilities of infection which exist.

Foot-and-mouth disease is not indigenous to this country, nor do I think it is indigenous to Europe, but it has been known in the East since the dawn of history. It is much more frequent on the Continent than in the United Kingdom, and when it appears in Western Europe there is always the chance of outbreaks occur-

ring in the United Kingdom. In the early days of foot-and-mouth disease in this country, it was remarked that the disease was present on the Continent, and the question was then asked, as now, if the infection could be traced to traffic with the Continent?

The question has been raised as to whether birds may not have something to do with the spread of infection. We know that birds migrate and pass over long distances of sea and land, and that they make long journeys in quite a short space of time. It is possible that birds may carry the virus in their intestines, not that it necessarily increases in amount in the bowel, but infective material taken in with food may be voided in the droppings of birds. In Denmark they are inclined to consider the possibility of birds, sparrows, gulls, and jackdaws spreading infection. In Denmark, as in other countries, every possible route by which infection may enter the country is being considered, and every possible or probable route demands careful consideration and examination.

There are accounts of interesting experiments—and very suggestive—in Italy with flies. Some have considered as possible the fly as a carrier of infection in foot-and-mouth disease, as we know it is of the virus of other infection. Flies may not travel very far, but probably much farther than experiments show. They may be carried down the wind some considerable distance, and they move on their own initiative more than 700 yards even across the wind. It is possible for flies infected with foot-and-mouth virus to go from one farm to another, from building to building, and cattle to cattle. The Italian experiments were with a tabanus, a biting fly. Flies were obtained from a region where foot-and-mouth disease existed, and were liberated in a house where clean cattle, which had been obtained from a non-infected district, and which had been some time under observation, were stabled. The flies were kept in captivity until hungry. They were then liberated and were seen to attack the cattle in the stalls. In three days symptoms of foot-and-mouth disease appeared. There appears to be little doubt in this experiment that the cattle were infected by the flies, and there is no reason to doubt the possibility of flies carrying the virus at this time of day, since we are now so familiar with many diseases, the causes of which are borne by mosquitoes, flies, ticks, etc., not to mention in polite society such social pests as fleas, lice, and bed bugs.

The question has also been asked if infection cannot be spread by manure. There is little doubt that recently passed faeces from infected animals may be infective to others, as pigs, which not infrequently devour the faeces of bovines, and it is possible that fresh faeces soiling litter and fodder and drinking water may prove infective to animals taking such. But can manure, *i.e.* stable and byre manure, infect after it has been stored in the usual way and then spread over land? Probably not, according to Loeffler's experiments. The temperature attained by manure heating in the mass is sufficiently high to destroy the virus. Virus was taken and placed in sealed pipettes and placed at various depths in a heap of fresh heating manure. The temperature reached by the fermenting manure was noted by the thermometer. It is possible for manure a foot or so below the surface to reach a temperature of 70 to 75 degrees C. (158 to 185 degrees F.) a temperature much too high for the virus of foot-and-mouth to survive. The contents of the pipettes were found to be sterile after a week or so. It appears to be a fact, then, that the heating of the manure is sufficient to destroy the virus. Probably new hay contaminated when being put into the rick will also become innocuous by the hay heating in the rick. It is different, of course, with old hay and straw which has passed the heating stage. Old

hay and straw may be contaminated from various sources, and on this the virus may remain uninjured for apparently a long time, as witness the Danish experience.

The main point or points I desire to emphasise is that food stuffs of all kinds may be infected directly or indirectly with the virus, and that such are capable of spreading and do spread the infection. It is possible also that the virus may be carried some distance by the wind, infective saliva may be blown some distance, certainly in the next pasture over the hedge, and when we remember the potency of the virus, a very minute quantity will suffice to set up infection. Probably also the ground—roads to wit, may become infected by the discharges of diseased animals which have passed over or along them. The virus may be transferred from one place to another not only by human agency; we all know the curiosity of people, the village parliament held whenever an animal is ill, and the examination made by the wiseacres of the district. Some Italian writers trace infection spreading from farm to farm to tramps, tinkers, and other wanderers who, sleeping about ricks and in barns, carry the infecting agent from one place to another. We know of the handy man called in to treat stock which the owner is too ignorant to do himself, or too negligent of his own interests to apply for help to his veterinary surgeon. Such persons handling animals promiscuously, and with little real knowledge of disease, are a serious menace to the live stock trade of the country, and I am surprised that the Ministry of Agriculture does not make some effort to suppress the quack. In addition to human agency, dogs and other animals, including ground game, may be vehicles for conveying virus from one part to another. We are all familiar with the vagrant dog and the distances he may cover in a night. When rabies was common with us in the United Kingdom we had plenty of evidence of the far afield excursions of dogs. It is believed by some that the infection may be water borne, and I see no reason to believe it is not possible. I can imagine animals with foot-and-mouth disease drinking at a stream, laving and washing out their mouths, the longropy strings of saliva flowing away on the surface of the water, entangled frequently in straw, or leaves, or what not, and eventually reaching other drinking places a long way down stream. And so on, we can conjecture many possible sources, or rather routes by which infection may reach a place.

The major problem, however, is, where does the virus come from? To this there is the certain answer which no one can gainsay, that the virus must have come from another case of the disease. There is no question of spontaneous generation; that is unthinkable at this time of day, at least among those who have given any thought to or had any experience of epizootic diseases. Every cell from a cell, every animal from an egg, every infectious disease from a similar infection, a common cause operating in every instance of the same disease. Anthrax and other bacterial infections are due to a specific cause, which can ultimately be traced to an animal infected by the same agent, the germ of the disease, and there is no reason to believe, though we have not yet seen the germ causing foot-and-mouth disease, nor have obtained it or grown it in pure culture, that it is any way different in its action from the cause, recognisable cause, as the bacillus of anthrax in the production of disease. That being so, we again come round to the ever recurring question, where does infection come from to reach the cattle in these islands? Is infection imported from abroad, and if so by what channel does it come? If not, how does foot-and-mouth disease escape the observation of the profession in the daily grind of its work? If foot-and-mouth disease were indigenous to this country, or had become a recognised—naturalised, if you will, disease, then we

could understand why it was more rife at certain times than others. But it is not indigenous, nor is it naturalised here. It is an invader—an alien. As I have previously remarked, an outbreak is dealt with by the authorities. Sick and in-contacts are destroyed, the centre of infection is wiped out, no animals, possible carriers of disease, are allowed to remain. If recovered animals were permitted to live, we could believe it possible they acted the *role* of carriers of the virus, but in the United Kingdom there can be no bovine carriers of foot-and-mouth virus. If evidence of this is called for, negative evidence alone is forthcoming, but it is as good in this instance as positive evidence; the disease does not as a rule appear a second time at the same farm. If it does very exceptionally, then there is an easily recognised reason, contaminated material, hay, straw, etc., has been allowed to remain.

It will be concluded from what I have said that we know little as to where infection comes from. I refer, of course, to initial outbreaks, isolated outbreaks when the country has been declared free from infection, and has remained free for months and years. The information we all desire is the source and the routes by which infection reaches our flocks and herds. There are many conjectures, there are not a few suggestions, but what we want are indisputable facts, and having got them we shall know what to do and when to do it.

Diagnosis. In the diagnosis of foot-and-mouth disease there are several factors to be considered. These are the character and site of the lesions, the number of animals affected and the species, and the history of the outbreak. Usually there is little difficulty in arriving at a diagnosis when the lesions are typical and a number of animals affected—bovines, and it may be sheep and swine. There may or may not be history of contact direct or indirect. In the absence of history one has to rely upon the characters of the lesions and their site, and the fact that a number of animals are affected simultaneously. I consider also the symptoms manifested are important, and due weight must be given to them. There are however cases arising in which there is room for doubt, where diagnosis is neither simple nor easy, and where caution must be exercised. If there is any doubt at all in the mind as to whether it is foot-and-mouth disease, it is wise to put restrictions into force until it can be shown definitely to be the disease or not. Little harm, though some inconvenience can be caused by putting on restrictions, but serious loss may follow failure to diagnose with no restrictions upon the movements of affected animals.

As everyone knows, there are cases of stomatitis occurring which are not due to the virus of foot-and-mouth disease. Stomatitis may be due to a variety of causes—infections of various kinds, mercurialism, fungi, etc. But these cases of stomatitis are not associated with lesions upon the feet, and if lesions occur upon the limbs they are not confined to the predilection sites of the lesions of foot-and-mouth disease, but rather they are of the nature of a spreading dermatitis extending upwards even to the body. Lesions may occur upon the udder in foot-and-mouth disease, but these lesions on the udder will be associated with lesions in the mouth or on the feet. Foot-and-mouth lesions on the udder without mouth or feet lesions are extremely unlikely. The udder lesions occurring with the greatest frequency in practice are the so-called "milk boils," which are truly boils, due to staphylococci, and lesions of cow-pox. Cow-pox lesions usually run a perfectly definite course which can be readily observed. In sheep, lesions of the feet due to foot-and-mouth disease are not likely to be mistaken, even when associated with the condition described as *impetigo facialis et labialis*. Any cattle or swine upon the same pasture remaining free from any lesions or symptoms will indicate it is not foot-and-mouth disease.

As to stomatitis, various forms have been described, but I will satisfy myself by describing the one observed in Ireland, discovered by the veterinary officers of the department and cleared up by the department in a series of experiments in which I was privileged to have a share. The stomatitis has no effect whatsoever upon the health of the animal, which apparently does not suffer any inconvenience at all. There are no mouth symptoms whatever. The animal feeds quite normally. The condition is noticed at the time of mouthing the animal, and until the mouth is opened and the condition of the mucous membrane attentively examined nothing is suspected. Sometimes the appearances presented are alarming, especially when one is "keyed up" and on the outlook for foot-and-mouth disease. But a little thought and a careful study of the facts will prove the difference. The lesion begins in the superficial epithelium of the lips, gums, or tongue. At first it is a brownish spot which enlarges peripherally. The epithelium involved separates off in flakes which are perforated (on the tongue) with apertures through which the papillæ passed. A number of lesions may begin simultaneously and extending eventually coalesce. They all show the brownish discolouration and exfoliation of the epithelium. Eventually the tongue shows large areas denuded of superficial epithelium, with broad low ridges of old epithelium persisting. These are the boundaries of adjacent lesions. In time all the old horny epithelium is lost and the tongue becomes quite clean and soft like that of a young calf. There never at any time is any exposure of corium, never at any time formation of vesicles, never at any time soreness of the tongue, drivelling of saliva or other sign of irritation. There never is any lameness or other lesion upon the body even remotely suggesting foot-and-mouth infection. The condition is found chiefly in young stock, rarely in full grown cattle, and it is not inoculable to sheep nor to swine as it is to young bovines. The condition is not one likely to be met with by ordinary practitioners, they will never be called in to treat it, and it is only likely to be encountered by those whose duty it is to mouth animals—to examine stock for mouth lesions of foot-and-mouth disease.

I could go on longer, but I am sure I have exhausted your patience. Still, any information we can give, and I hope to get a good deal of information from the discussion which will follow, will be of benefit to us all, whether we are practitioners likely to meet with the infection in our daily work in the field, inspectors under central or local bodies combating epizootics, or merely students and teachers watching and waiting for the facts collected by those immediately in contact with the disease.

DISCUSSION.

Mr. TRIGGER initiated a discussion, and said he had listened with intense interest to the very up-to-date address which Prof. Mettam had given. It was very difficult to know, as they had just been reminded, how foot-and-mouth disease came into the country. He was taught, as a student, that the first outbreak in England was in 1839, and it was not until 1842 that any imported cattle were brought into this country. At that time the disease had been raging in Hungary, Italy and Germany, and it reached these coasts three years before any cattle came. The suggestions of Prof. Simonds in those days were as Prof. Mettam had said, cattle might have been smuggled into England, or an odd cow might have been kept on board ship to give milk to the sailors. We were also told that gallinaceous birds were to be watched with suspicion. He (the speaker) did not accept the theory that foot-and-mouth disease occurred in man. He had never seen it in man, or anything that could be likened to foot-and-mouth disease in man. In the early days, when the authorities were not very

particular, Dr. Erasmus Wilson experimented with children in St. Pancras workhouse without any ill effects. Again, he had never seen it in dogs, but he had seen it in hundreds of cattle, sheep and pigs. Prof. Simonds told him that dogs could eat the flesh of affected animals with impunity, but he agreed that they might be carriers of the disease. When they considered the virulence of the disease, it was easy to imagine that a little saliva falling on a leaf and being blown from field to field, would help to spread the disease, and that under those circumstances it would be most difficult to stamp out.

Everyone would agree with the diagnostic symptoms which Prof. Mettam mentioned, but as an old practitioner who had seen a lot of the disease in his time, if they were to put him (the speaker) blind-fold in a cowshed he could tell them whether foot-and-mouth disease was present or not. Stand still, and they would hear a sound which he could only compare to a young man kissing a young lady very heartily. There was a very distinct smack. The shaking of the feet was another characteristic which there was no mistaking.

Prof. Mettam had spoken of the extraordinary rapidity with which ulcers healed. One need not open the mouth; just look at the top lip or the tip of the tongue. For some time the ulcers left a very characteristic lesion for 12 or 14 days; the ulcers as they disappeared left an ugly scar or dry scab. In pigs the lesion was not in the mouth but on the outside of the lips and on the feet, and the mammary glands of suckling sows became very badly affected.

The restrictions which had been enforced, though very severe, had been abundantly justified. If a man got the disease in his stock at all it went right through, it was not confined to one animal. Complete isolation and the most drastic treatment had proved the best means of combating the trouble.

Mr. LAITHWOOD said they had yet a great deal to learn on this subject, and he thought there was work for a Royal Commission. Foot-and-mouth disease had been very rare since he commenced to practice, and therefore he knew very little about it, but he was interested in what Mr. Trigger had said as to being able to diagnose it blindfold.

Mr. A. OVER said that in the few cases he had met with he had found the feet more troublesome than Prof. Mettam had suggested. He had not seen the disease in sheep.

Mr. GOLD said that as a former colleague of Prof. Mettam it gave him great pleasure to welcome him at a meeting of the Midland Association. "I was interested in what he said about the incubative period being from two to four days," proceeded Mr. Gold. "I would like to mention a peculiarity in connection with the outbreak at Redditch, and I think there was no doubt in the minds of the veterinary profession that it was a typical case of foot-and-mouth disease. These animals, 12 good bullocks bought in Ireland, were landed at Birkenhead, and kept there under observation for eight days. Then they were passed on to my district as being free. The owner had these beasts on the Tuesday. On the Sunday he told me what had taken place, and asked me if I thought they were free. I said that my experience was limited, but I did not think he was free because there was a possibility of the lairages at Birkenhead being infected. No sign whatever was seen of these bullocks being infected till the Friday following, when two animals were affected with foot-and-mouth disease. It was strange to me. I had always understood that the incubative period was from two to six days at the most, and I feel confident that the disease was picked up after the animals left Ireland. They probably became infected at the lairages at Birkenhead, because they were there for eight days, and then it was another ten days before

they developed the disease. I think it is only reasonable to believe that they did not get it in Ireland."

Mr. MARTIN said that in 1881 he saw 600 Canadian cattle in the docks at Glasgow affected. Hardly one escaped. Soon afterwards, he went into Cheshire, and there was a very bad outbreak there. The London and North Western Railway ran through the farm, and it was believed that something was thrown out from a passing cattle train that caused the trouble. He had never seen such a horrible and pathetic sight in his life as the sight of those animals suffering. Nowadays, he was glad to say they were spared that experience, because all affected animals were slaughtered immediately.

Mr. TIPPER said there was another aspect of the matter upon which he would like to speak. Prof. Mettam had mentioned the possibility of the disease being disseminated by means of hay and straw and food stuffs. He (the speaker) recently brought to the notice of the Board of Agriculture and the Royal Agricultural Society the fact that ground dried livers of animals had been sent over to this country from abroad to be used as food stuffs. It had occurred to him that there was a possibility of the disease, or of any other disease for the matter of that, being communicated in that way. He would like to ask Prof. Mettam whether foot-and-mouth disease was prevalent in China, because if so that might be another source of infection. In going round farms he had noticed young paying particular attention to pigeons, and he fancied pigeons might be another means of spreading the infection. As a member of the Executive Committee of the Worcestershire County Council he was particularly interested in this subject, and information upon it, especially in relation to its origin and source, would always be welcomed.

Mr. FORSYTH said it was 30 years since he saw a case of foot-and-mouth disease, but he would like to mention a few cases that occurred in dogs. The opinion of the late Prof. Williams was taken and he declared that the trouble was foot-and-mouth disease. It was very prevalent at the time, and he had never seen anything like it. He also saw some hares with similar vesicles on their feet and that might help to account for the disease spreading. He had seen animals with lesions in the mouth and on the coronet, and had also noticed them shaking their feet, but he had never noticed the "smacking" sounds referred to by Mr. Trigger. He could endorse all that had been said about the rapidity with which the lesions healed. His first experience of the disease was when he was assistant to the late Mr. Olver, and he thought he was looking at a different lot of cattle altogether to what he saw a few days before.

Mr. DEVINE said he had not had much experience of the disease, but of course he had studied it to some extent, and there were one or two points raised by Prof. Mettam which were new to him. The Professor had referred to stomatitis affecting cattle in Ireland which was at first thought to be foot-and-mouth disease, but which proved not to be so. It was evidently different from the ordinary stomatitis they met with in cattle. As far as he knew, and what he had read, it was a very extraordinary thing to get an isolated case with one or two animals affected at a farm. Foot-and-mouth disease was such a wildfire thing that it got all over a large area before they knew where they were. He had not had the experience of those who saw all those cases that occurred thirty or forty years ago; he had seen the dried specimens in the laboratory, and, speaking theoretically, where they got one case of foot-and-mouth disease they probably got 20 reported that were not. He should be glad if Prof. Mettam in his reply would explain the difference between the stomatitis in the North of Ireland which was mistaken for foot-and-mouth disease and the stomatitis which they ordinarily met with in their country practices.

Mr. BURCHNALL said that as the symptom mentioned by Mr. Trigger had been made fun of, he might say that 35 years ago, when he was practising in Derbyshire, the disease was known locally as "the smack." He was very young in the profession then, but he did a lot of inspecting and he could bear out every word that Mr. Trigger had said. A characteristic shake of the hind foot and a decided smacking sound with the mouth was considered a pretty safe diagnostic in those days. He also remembered when he was a boy at his own home they had cattle suffer twice in the same year from the disease, in the spring and in the autumn. It affected the feet of sheep decidedly more than the mouth, but in the case of cattle it affected the mouth more. His father was a sheep breeder and their greatest trouble was the appearance of the disease in the neighbourhood.

The PRESIDENT said he could not sufficiently thank Professor Mettam for his address, which was one of the best and most instructive they had ever listened to. The subject, too, was of profound interest to them all. The present action of the powers that be stamped the disease out very rapidly, and herd owners were protected from the loss which the ravages of the disease inflicted a generation or more ago. At the same time he thought the Board of Agriculture were a little remiss in not giving the younger members of the veterinary profession an opportunity of seeing the disease. (Hear, hear). He had done his best to get the Board to show it to their members, but to no purpose; he was told that he could see specimens in the bottles in the laboratory. It was to be regretted, because they could best learn by studying the disease first hand.

REPLY.

Prof. METTAM thanked the meeting for the kind reception they had given to his paper. Mr. Trigger had referred to what occurred in the early part of last century. Foot-and-mouth disease was not prevalent in this country till about 1840, but from that time onwards there was a series of outbreaks every ten years or so up to 1880, when there was a tremendous big outbreak which lasted for three years. There was no doubt that foot-and-mouth disease was raging on the Continent prior to 1839, and veterinary surgeons in this country were familiar with the fact. Long before then foot-and-mouth disease raged on the Continent, and as long ago as 1814 it was suggested that people should inoculate their cattle against it, and the way they did it was a practice in vogue in Europe at the present time. They wiped out the mouth of the infected animal with a cloth and then allowed the other animals to chew this cloth, and they became infected; or they took a wisp of hay soaked with infected saliva and rubbed it into the mouth. Mr. Trigger doubted whether foot-and-mouth disease occurred in man, but he (the Professor) thought there was no doubt about it. He could tell them of a case where material was taken from vesicles that developed in a man and inoculated into a calf, and the calf developed foot-and-mouth disease. Mr. Trigger also demurred at the suggestion that the disease appeared in horses and dogs, but he thought Sir Stewart Stockman had seen it in the dog, and it had been clearly seen in the horse. He had not mentioned all the symptoms of the disease in his paper, but he always understood that smacking of the lips and shaking of foot were diagnostic signs. He was extremely pleased to hear Mr. Gold's account of the Redditch cases. He had heard of them in Ireland, and could not understand, if they contracted the disease in Ireland, how it was they should defer showing signs of it so long. It must have been 18 days after they left Ireland before the disease manifested itself. Obviously, the disease was contracted in the lairages at Birkenhead, if not later, and Mr. Gold's

story confirmed his view that the trouble was not traceable to Ireland.

Mr. Tipper's contribution to the discussion was extremely valuable. This question of imported dried flesh of different kinds was of great importance. He had had no experience of ground dried liver, but he knew of ground fish meal, which was somewhat similar, and apparently in Germany a number of cases of anthrax in swine had been attributed to it. Mr. Tipper asked if there was foot-and-mouth disease in China; he could not answer that question positively, but it was a matter that ought to be looked into, as a lot of food stuffs came into this country from China, even pork for human consumption. Mr. Forsyth's remarks were interesting as regards the presence of vesicles on the feet of hares, as it confirmed his view that ground game was a ready means of spreading the disease. Mr. DeVine wanted to know more about stomatitis. He had tried to be clear as to that which he saw in Ireland, but there were many different forms of stomatitis, and such cases arose from different causes. In the Irish case, the trouble was of such a mild nature that no one would believe that the animals were suffering from anything at all, and it was only when one took out their tongues that one could find anything wrong with them. The animals were thriving in the best condition in the field, and farmers in the North of Ireland, like farmers in the Midland Counties, were not likely to employ a veterinary surgeon to treat an animal that was not suffering from anything serious.

Votes of Thanks. The HON. SEC. moved a vote of thanks to Prof. Mettam, and said that they must all have appreciated the address they had listened to. It was full of information that was useful and quite up-to-date. Prof. Mettam occupied a very honoured position in the veterinary world, and this Association was glad to welcome him in their midst.

Mr. DeVine, in seconding, said he was the first student to go to Prof. Mettam in Ireland, after previously starting his career under him at Edinburgh, and he looked upon Prof. Mettam to-day as a close personal friend.

Mr. Gold and the President briefly supported the motion, which was heartily carried.

A vote of thanks was also accorded to the President for his services in the chair.

SPECIMENS.

Mr. YOUNG brought some interesting post mortem specimens of cases that had recently occurred in his practice. One was a dislocation of the femur in a horse where the head of the femur was totally worn away. Another case was a fractured pelvis in a dog.

The members had tea together before separating.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

The Diagnosis of Glanders.

The February Bulletin of the Department of Health of the City of New York gives an account of the methods of diagnosis there employed. Human deaths from glanders in New York average about 3 a year, the highest number recently being 5 in 1912, and the lowest 1 in the following year. When a case of glanders is recognised in a stable, blood is taken from all the other horses and examined by the complement-fixation test. This is analogous to the Wassermann reaction as used in the diagnosis of syphilis, the antigen being prepared from pure cultures of bacillus mallei. If a positive reaction is obtained, the animal from which the blood was taken is then examined further by means of the conjunctival test, analogous to Calmette's reaction in tuberculous human beings, four or five drops of undiluted mallein being dropped into the conjunctival sac. In

infected horses a reaction commences within six or eight hours and may last from 36 to 48 hours, the eye becoming inflamed and giving rise to a purulent secretion. These two tests applied together are held to give a certain diagnosis, and animals which react to both are destroyed on the strength of them. Other tests for the disease are the intradermal method of injecting mallein, by which a localised swelling in the skin is produced in infected horses, and the agglutination reaction, in which a positive result in a dilution of 1:1000 or over is held to indicate the existence of glanders. The original method of subcutaneous injection of mallein does not seem to be now so often employed, but with care it is also capable of giving reliable results, a rise of temperature of not less than 2.5° F. being considered positive evidence, the temperature of the horse's body rising to at least 103°. Horses which have been exposed to infection, but which give a negative reaction to the tests used, should be examined again after 15 days' interval. It seems that the agglutinins are the earliest antibodies to appear in the course of the infection, being present within the first four or five days. The specific amboceptors upon which the complement-fixation test depends are likely to appear within a week or ten days after infection, while the conjunctival reaction cannot be relied upon to appear before the lapse of three weeks. It must further be remembered that an injection of mallein for diagnostic purposes may itself give rise to the formation of antibodies, which may remain for six or eight weeks, while a vaccine of glanders bacilli may cause the continued presence of these bodies for a period of three months or more.—*The Lancet.*

Hunting Memorial Fund.

Subscriptions received up to 7 p.m., May 27th, 1914.

	£	s.	d.
Amount previously acknowledged	302	18	6
Mr. A. Spreull, sen. (F), Ward Rd., Dundee	1	1	0
J. Spreull, Umtala, Cape Colony	1	1	0

The Midland Counties Veterinary Assoc., per			
J. J. Burchnall, Esq., Hon. Treas.	10	10	0
	£316	11	6

In the list of subscriptions received it was stated in *The Veterinary Record* of Jan. 31st, that Capt. E. C. Russell, A.V.C., Quetta Club, India, had subscribed £1 ls. to the Fund, whereas the amount actually received was half-a-guinea.

In the list of May 13th, 1914, Dr. J. G. Rutherford's subscription should have been £1 ls., and not £1 0s. as stated.

The total amount received up to 7 p.m., Wednesday, May 27th, 1914, is therefore £316 2s.

HENRY GRAY, Hon. Sec. & Treas.

An Advance in Crystallography.

Ocular evidence has been obtained which substantiates the modern theory of crystal structure upon the position of the atoms. By passing, for example, the X rays through a crystal an interference photograph is obtained of what is called the space lattice of the crystal. It would appear that this has afforded the first visible proof of Dalton's atomic theory.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, May 26.

TERRITORIAL DECORATIONS.

The King has been graciously pleased to confer the Territorial Decoration upon the following Officers of the Territorial Force, who have been duly recommended for the same under the terms of the Royal Warrant dated Aug. 17, 1908:—

* * *

ARMY VETERINARY CORPS.

Major J. W. Coe.

Personal.

ROWSTON—PORTER.—On May 12th, at St. Peter's Church, Dorchester, by the Rector (the Rev. H. C. Coote), Capt. William Neville Rowston, A.V.C., son of Mr. and Mrs. Robert Rowston, of "Casterbridge," Dorchester, to Eveline Louie, second daughter of the late Mr. William Henry Porter and of Mrs. Porter, of Icen Cottage, Dorchester.

PAINE—BULL.—On May 16th, at East London, Cape Colony, Florence Bull, of Kensington Park Road, Bayswater, W., to Richard Paine, F.R.C.V.S., of Bessels Green, Sevenoaks.

MR. T. R. R. HOGGAN, M.R.C.V.S., of Vancouver, B.C. was judge at the Spring Show of the Irish Terrier Club of the Pacific Northwest, held in the second week of May, at Seattle, Washington State.

OBITUARY

E. H. SCOTT, M.R.C.V.S., 727 High Road, Leyton.
Graduated, Lond: July, 1881.

Mr. Scott died suddenly on May 26th Aged 60 years.

MR. NORMAN C. CARUTH, Solicitor, Ballymena, County Antrim, Ireland, asks that any person having any documents relating to the late Major Millar's estate will please communicate with him.

CORRESPONDENCE.

NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

Sir,

In reply to "A" Mr. Spencer in your last issue, may I say he should have done me the justice to have quoted the whole passage in full, as it appeared in the report of the Royal Counties meeting, but that would not have suited his purpose. Even then he would not have been quite correct. What I did say was "The idea seems to be pretty general that the National Veterinary Inspectors' Association appeared to be *non est*, nothing tangible having been done by them of late." I might have added, had I been the selfish individual he wishes to infer, "That it were better it had never been born" with perfect truism, inasmuch as the first evidence of its existence was the reduction of the scale of fees allowed us by our County Council and Municipal bodies to the tune of 33 per cent.

We accepted the result of this policy of "levelling down" without a murmur, after having done our best at the general meetings and in Committee to keep the process within reasonable limits in the general interest.

In my advocacy of Inspectors' Sections at each meeting I have visited I have stated "that any matter of sufficient importance discussed at these sectional meetings could be handed through myself to either of the National Societies—having hitherto regarded the National Inspectors as an affiliated body—and on two of these occasions I have been met by the statement that the latter body was practically defunct, at any rate it had given no evidence of existence of late; further, many applications have been made to me by veterinary inspectors, widely distributed, and by two County County clerks for copies of the Kent scale and the pamphlets issued by the National Veterinary Association, nothing else being obtainable, apparently. From this you may judge there is some real reason for the apology to a "few members" of whom *fortunately* I am not one.

I am fully aware of the labour of drawing up and tabulating a list of fees. The real labour is in getting replies. This has been done for Mr. Spencer by the National V.A. months prior to the existence of the N.V.I., who utilised the scale and other information thus obtained for their effort—with scant acknowledgment—unless I may take his letter as such.

My object in advocating sectional meetings at Societies is to unite the profession, thus preventing, to some extent, that conflict of opinion and jealousy which exists to-day between those who are, and those who are not veterinary inspectors, and which causes that fear of "asking for more" with any insistence, inspectors knowing full well there are plenty ready to accept existing conditions—or even less. The policy of dividing the profession into two bodies, inspectors and non-inspectors, by a fine line is, to my mind, a folly, and will only tend to increase this unsatisfactory state of affairs. Without an Act of Parliament it will be impossible to force any local authority to adopt any particular scale; the bargain still has to be made between the local veterinary inspectors and the local authorities, as Mr. Simpson in his letter—which I, too, particularly wish you to read—clearly shows. I can see no reason why veterinary inspectors should not combine, as I suggest, excepting that shadowed forth in his letter—that it may be the intention of the N.V.I. to form independent sub-branches—the very thing he apparently deprecates in the next paragraph.

Now what is this "most important communication" to which I, as a Vice-President of the N.V.I.A. have neglected to reply? The only document I have received that needed one was a query as to the fees paid by local authorities in Kent—a practically useless one so far as we were concerned. They were well known to Mr. Spencer and every one interested. However, it was answered. I arranged, and Mr. Crowhurst, the President of the South Eastern Veterinary Association, undertook to fill in his form which applied to the whole of us—a collective answer perhaps Mr. Spencer did not appreciate fully. Had Mr. Spencer had as many opportunities of hearing what has been said regarding the inaction of the N.V.I.A. as I have had, he would have come to the same conclusion many others beside myself have done—"that the Society appeared to be practically *non est*." If my pin-prick has aroused it from somnolence I am glad. I have no wish to attend its obsequies as your generous (?) correspondent seems to think.

The real object of Mr. Spencer's letter is too patent to need comment—beyond that it may defeat its own ends. Thanking you—I am, yours very faithfully,

THEO. C. TOOPE.

CORRECTIONS.

In last week's issue, p. 766, in Mr. Morris's reply, 25 lines from top of first column, the passage should read: "diluted by the whole volume of the blood. Where, on the contrary, the inoculation has been made (if I may so express it) *up stream* from the focus of infection," etc.

In Mr. John Brown's letter, p. 767, second line above the prescription, "and in one goat," should read, and in one foal.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1352.

JUNE 6, 1914.

Vol. XXVI.

THE ANNUAL GENERAL MEETING.

Little need be said of the annual general meeting, and that little cannot be complimentary to the profession. Everything had encouraged the hope of a good meeting—the fine weather, the important and varied report to be discussed, and the absence of a counter-attraction at Epsom. Despite this the attendance was little, if at all, better than usual, and there was practically no discussion. More than half of those attending were past or present Councilmen or examiners—another illustration of the indifference of ordinary members to our annual meeting.

Time will show whether the projected readjustment of the date of the meeting by our next Charter will enable better meetings to be obtained, but we do not hope much from it. The date of the meeting has been altered by Charter before, and the result was not what had been hoped. What is needed far more than any change of date is that members generally should shake off their apathy towards the public affairs of the profession. The most fatal evidence of that apathy is the fact that the few men who do attend these meetings are, to a very large extent, the same men year after year. Almost every man present last Wednesday was known to all the rest. Nearly all were regular attenders at the annual meeting, though only about half were Londoners. When we consider how large a proportion of every annual meeting is made up of these few regular attenders, the indifference of the rest—especially the London ones—becomes a disgrace to the profession.

JOHNE'S DISEASE.

"Our Birmingham abattoir statistics show that nearly as many carcasses are condemned from Johne's disease as from tuberculosis." These words in Mr. Malcolm's presidential address, printed last week, must have surprised many. Most of us agree that Johne's disease is more common than we know, but few thought it to be so common as this. Coming from such an authority, the statement should lead practitioners who have not yet seen much Johne's disease to search for it carefully. It should be remembered that the disease was first recognised in England less than ten years ago, that it certainly existed long before that and was often mistaken for tuberculosis or parasitism, and that it may quite conceivably be often so mistaken still. More searching enquiry may indicate the advisability of scheduling it.

FRACTURE OF THE OS PEDIS TREATED BY BIER'S METHOD.

Lemère and Ducrotoy record (*Rev. Vet Militaire*) the case of a fifteen-year-old mare which, after an accident in the riding school, showed very severe lameness.

The foot was warm and very sensitive, rotatory movements of it caused excessive pain, and to bear weight upon it was impossible. The injection of cocaine on both sides of the fetlock joint caused the disappearance of the lameness. After some days the diagnosis of fracture of the pedal bone was made.

The treatment consisted in warm foot-baths and the application of a Bier's bandage in the middle of the cannon region for a period of ten hours daily. After twenty days a groove was made round the hoof beneath the coronary cushion, and the coronet itself was sharply blistered.

Two months after the accident all the lameness had disappeared. Afterwards the mare died from a meningo-cephalitis, and the pedal bone was examined post-mortem. It was found that a triple fracture had occurred, which had become united by a callus projecting relief-like from the bone.

The authors conclude that it is indicated, in a phalangeal fracture, to make use of the nutritive and regenerating effects of venous hyperæmia. —(*Berliner Tier. Woch.*)

A CASE OF MAMMARY TUBERCULOSIS.

H. Bombard, of Weidenberg, a district veterinary surgeon, records the following case. He was called to a cow which he was informed had calved three weeks before, and since that time had had a swollen udder. The appetite and general condition were good. Bombard's examination revealed a hard solid enlargement of the udder without the formation of nodules. The anterior teats were only giving a little milk, and the posterior ones none at all. Bombard gave the opinion that a complete recovery could not be expected, and that at the most a partial reduction of the swelling might be attained.

The treatment adopted was the rubbing in of a 10 per cent. iodine ointment, massage, warm potato poultices, and frequent milking out. Four days later the owner reported a general deterioration. The cow had almost ceased to eat for two days past, she gasped a good deal, the udder was still more swollen than before, and the animal showed more pain. Bombard at first thought of iodine poisoning, but a clinical examination gave no support to this view. During the next fortnight the

cow became very thin and had scarcely any appetite, and therefore she was slaughtered.

Post-mortem examination revealed tuberculosis of the udder, and miliary tuberculosis of almost all the internal organs. Bombard suspects that the tubercle bacilli were forced into the blood stream by the massage and rubbing of the udder, thus causing generalisation. He remarks that an examination of the milk might perhaps have led to a diagnosis of tuberculosis, while on the other hand, the absence of nodules from the swelling, its short duration, and the fact that it had arisen at parturition, rather indicated an infection by some other agent than the tubercle bacillus. He adds that the case is a warning against treatment by massage in any inflammations of the udder which may be of tuberculous nature.—*Munchener Tier. Woch.*

CIRCULAR RESECTION OF THE TRACHEA AND PRIMARY SUTURE.

Josef Mares, of Brunn, reports (*Esterreich. Wochenschr. für Tierheilk.*) the results of experiments he has made in the operation of removing portions of the trachea by circular resection and uniting the fresh healthy cut surfaces of the tracheal wall by a suture. The fact that stenosis of the trachea is a not infrequent result of tracheotomy in the horse led him to make these experiments. As experimental material he used four horses (anatomical subjects) and four dogs. In his article he sketches the anatomical relations of the trachea, and discusses the operation and its indications, the clinical course, and the pathologico-anatomical and microscopical results, and finally he arrives at the following conclusions:

1. The most advantageous method of removing stenosis of the trachea consists in total circular resection of the stenosed portion, followed by primary suture of the trachea.
2. In the posterior half-periphery of the trachea the sutures should be internal, and in the anterior half-periphery external.
3. Iodized catgut is a very good suture material.
4. The operation should be performed with the head hanging downwards.
5. Prophylactic tracheotomy below the site of the operation is not necessary.
6. In the after treatment, it is absolutely necessary that the head and neck should be fixed in a bent position.
7. As regards the length of the portion of trachea which may be removed in the horse, Mares' experiments upon the dead subject led him to fix six tracheal rings as the maximal limit. This length suffices for even the most extensive stenoses.—*Berliner Tier. Woch.*

BOVINE ANTHRAX OF THE LYMPHATIC GLANDS.

Haffner, director of the abattoir in Düren, records (*Zeitschr. f. Fleisch u. Milch-hygiene*) a case of this nature. The existence of anthrax was bacteriologically proved beyond all doubt, and the case is noteworthy because it shows that the

hæmorrhagic "necrotising" inflammation of isolated lymphatic glands which is regarded as pathognomic of anthrax in swine occurs also in the ox.

The subject, a cow, showed symptoms suspicious of anthrax, which completely subsided. A swelling upon one side of the neck then developed, and the cow was slaughtered on account of lack of milk. Post-mortem, the spleen was found moderately enlarged, and hard and firm in consistence. The tissues pertaining to the swelling in the neck were saturated with a hæmorrhagic jelly-like material.

The left submaxillary lymphatic gland, and some lymph vessels lying in the region of the pharynx, œsophagus, and trachea were enlarged to many times their normal size. Upon section, they were friable and their inner layers were brick red. The left retropharyngeal lymphatic gland was the size of an apple, and showed the most marked lesions of anthrax. The left tonsil was considerably enlarged, and upon section it showed "marblings" similar in colour and nature to the affected lymphatic glands.—*Berliner Tier. Woch.*

TUMOUR IN A HORSE'S RECTUM.

Leicht, of Isen, records the case of a two-year-old stallion, which was attacked by colic in the evening. At first the most striking symptoms of illness were sweating, violent straining to defecate, and a moderate degree of restlessness. Rectal examination was carried out the same evening, and yielded a surprising result. About nine or ten inches in front of the anus a swelling the size of a man's fist could be felt projecting from the right wall of the rectum and narrowing the rectal lumen. The fæces were impeded by this new growth to such a degree that the balls of dung were firmly pressed together, and could only be removed gradually, in small portions, and with difficulty. The new growth itself was smooth upon its surface, covered with mucous membrane, and insensitive. It felt elastic, and could be drawn forward to a certain degree. Its form was egg-like, but somewhat flattened on two sides.

At first the treatment consisted in manual removal of the faecal masses in the rectum, and the administration of a light purgative and soft food. The next day an iodine preparation (iodvasoliment) was applied to the new growth by the following method:—A tube of durite was fastened by one end to the needle of an injection syringe, and the other end was fitted to the mouth of the syringe. Syringe and tube were then filled with iodvasoliment. The needle and part of the tube were introduced into the rectum. The needle was inserted into the centre of the growth, and then turned in four different directions, while, by the help of an assistant, the contents of the syringe were gradually injected. About 6 c.c. of the iodvasoliment were thus introduced into the tissues of the growth.

The result was favourable. After eight days the swelling had shrunk to half its former size, and after three weeks it could scarcely be felt. There was no recurrence. During the first eight days the horse only received soft food in small quantity.

After this time the earlier feeding was resumed, and the horse was put to light work.

The author suggests that the tumour may have been a lymphadenoma or a lipoma, but remains uncertain on that point.—*Münchener Tier. Woch.*

W. R. C.

Royal College of Veterinary Surgeons.

ANNUAL MEETING.

The Seventy-first Annual General Meeting was held at the College, 10 Red Lion Square, London, W.C., on Wednesday, June 3rd. The following members signed the attendance book :—Messrs. N. Almond, G. A. Banham, Dr. O. Charnock Bradley, Lieut.-Col. E. R. C. Butler, Messrs. J. Basil Buxton, W. Roger Clarke, J. C. Coleman, F. W. Garnett, F. L. Gooch, Sir John M'Fadyean, Messrs. H. A. MacCormack, W. J. Mulvey, T. Salusbury Price, William Reekie, Jas. Rowe, William Shipley, Sidney Slocock, Sir Stewart Stockman, Mr. Arnold Spicer, Maj.-General F. Smith, Messrs. Sidney Villar, John Ward; Mr. G. Thatcher (Solicitor), and Mr. Fred Bullock, (Secretary).

Mr. MULVEY : I understand that the President is unavoidably absent, and in his absence I move that Mr. Salusbury Price, Senior Vice-President, take the chair.

Sir JOHN M'FADYEAN : I second that.

The resolution was put and carried.

The chair was then taken by Mr. T. Salusbury Price.

The CHAIRMAN : Gentlemen, I can assure you that being thrust into this position I feel a heavy responsibility has been put upon me, and if I had had the slightest idea I should have been placed in this position I should have been late this morning! Still, as I am here I will do the best I can. The first business is for the Secretary to read the notice convening the meeting.

The SECRETARY read the notice.

APOLOGIES FOR ABSENCE.

The SECRETARY : I have to report that the President writes regretting his inability to attend the meeting to-day, and presenting his apologies to the meeting. Letters of apology have also been received from Mr. A. W. Mason, Mr. J. Clarkson, Maj.-General Thomson, and Prof. A. E. Mettam, members of Council.

MINUTES.

The SECRETARY read the minutes of the last annual meeting, which were confirmed.

ELECTIONS TO COUNCIL.

The SECRETARY read the following Scrutineer's report: "Election of eight members of Council, June, 1914. We certify that the votes recorded in the voting papers for the several candidates nominated for election to Council were as follows :—

Shipley	998	Mason	897
Sumner	972	Howard	826
Abson	925	Banham	764
Brittlebank	914	Coleman	734
Toope 640.			

There were two spoilt papers and 46 papers were received too late." The report was duly signed by the scrutineers.

The CHAIRMAN : I have much pleasure in declaring the following gentlemen elected members of the Council : Messrs. Shipley, Sumner, Abson, Brittlebank, Mason, Howard, Banham, and Coleman.

We now have to pass a vote of thanks to the scrutineers. This scrutineering business is arduous work. The scrutineers come here every year, and it takes three or four hours hard work to count all the votes and I think they deserve our praise.

Mr. JAMES ROWE : I beg to propose a vote of thanks to those gentlemen.

Mr. REEKIE : I second that.

The resolution was carried unanimously.

The CHAIRMAN : We now come to the annual report and financial statement. The latter part is rather black, but still we must live in hopes. Will somebody propose that the annual report and financial statement be received?

Mr. H. A. MACCORMACK : I propose that the annual report and financial statement be received.

Mr. JAMES ROWE : I second that.

The resolution was carried unanimously.

Mr. GOOCH : I now move the adoption of the annual report and financial statement. There is one question I should like to ask with regard to the new Supplemental Charter referred to on page 3 of the report. I think the first Clause of the new Supplemental Charter leaves the date of the annual meeting in a rather indefinite way; it says it "shall take place on any of the first seven days in the month of June." I think that might have been worded a little more definitely. I suppose that has been done in order that we may get away from the idea that a good many veterinary surgeons say they have to go to the Derby instead of coming to the annual meeting. If the annual meeting was fixed on a Thursday it would do away with all that. The provincial practitioners are very busy at this time of the year, and I think it leaves it in a very indefinite way to say that the annual meeting may be held any day in the week. There is nothing to hinder the President calling it upon a Sunday.

The CHAIRMAN : We should give you notice, specifying the day and the time.

Mr. GOOCH : But it might be a short notice.

The CHAIRMAN : No, we have to give the legal notice—a fortnight's notice. You have plenty of time.

Mr. GOOCH : I should like to suggest to the Council that we fix a certain day of the week, say Thursday, for the holding of the annual general meeting. I think that is convenient to most members.

The CHAIRMAN : All these suggestions will be taken notice of in due course.

Mr. W. W. REEKIE : I second the motion for the adoption of the report.

The CHAIRMAN : Gentlemen, it is now open for discussion. I think the best way will be to go through it page by page. (The Chairman then called for discussion on the report page by page, but none was forthcoming.) Well, gentlemen, I can only say it only shows what confidence you have in the members of the Council.

The resolution for the adoption of the report and the financial statement was then put and carried unanimously.

The CHAIRMAN : Gentlemen, that concludes the business of the meeting.

Mr. MULVEY : Before you vacate the Chair, sir, I was going to ask the members who are present to pass a very hearty vote of thanks to you for the way in which you have stepped into the breach caused by the absence of our President. I therefore move that a hearty vote of thanks be given to Mr. Price for the way in which he has carried out the duties of the Chair.

Mr. BANHAM : I beg to second that.

The resolution was then put and carried by acclamation.

The CHAIRMAN : Gentlemen, I return you many thanks. I am very sorry that I have shown a few shortcomings while occupying this position, but if I am thrust into it at any future time I hope the little experience I have had to-day will be the means of enabling

me to acquit myself better than I have done this morning. I return you many thanks, and I hope to have the pleasure of meeting you all this time next year looking as well and happy as we are at the present time, as I trust by this time next year we shall be able to record some improvement in our Finance Department. The Treasurer is not very happy, although he looks very happy. (Laughter.) Still, these small things do not interfere with him, and we feel that if we get short of money we have only to go to the Treasurer and he will find it. I return you many thanks for your presence here to-day.

SOUTH EASTERN VETERINARY ASSOCIATION.

[NATIONAL V.M.A.—SOUTHERN BRANCH].

INSPECTORS' SECTION.

Meeting held at Tonbridge, May 13th.

Mr. CROWHURST: I wish to bring forward the question of charges for final visit and examination in cases of mange. It is in reference to the examination of a horse supposed to be recovered from parasitic mange. I put in my charge of 10/6 considering that it was an examination of importance which had to be very carefully made, and which had a certain amount of responsibility attached to it, for if we made a mistake we might spread the disease throughout the district, and be called to order in consequence. I was written to very quickly afterwards and asked why I had charged 10/6 instead of 5/-. I stated that I understood others had charged 10/6, and that it had been passed, and therefore could not see why they took exception to my charging that sum. It is a small matter, but if we unite, as we have done on former occasions, we shall benefit to some small extent. I propose: "That the Association adopt the fee of 10/6 instead of 5/-, and that the Secretary be asked to write to Mr. Prosser, the Clerk to the Kent County Council laying before them the facts."

Mr. HOBGEN seconded.

Mr. COLEMAN: I should rather like to mention one thing which appears to me to be of importance to the profession generally. You seem to be in a happy position in Kent. In Wiltshire we get no second fee at all. I think there ought to be some measures taken to see that the fees for the whole country are more uniform. In one county the one mode of administration, and in another county another.

Mr. MORRIS: I think we are better off than you in Kent. For a case of parasitic mange I get 10/6.

Mr. TOOPE: This shows the advisability of adopting our system in other societies I mentioned the other day. We ought to get paid by our county, and not by our clients.

The resolution was carried.

Mr. MORRIS: The East Sussex inspectors had a meeting at Brighton, and the County Council made inquiries and raised our prices to practically what we wanted.

Mr. GREGORY: So far as the general fees go, I think owing to the exertions of several gentlemen connected with this Association, we ought to be satisfied. There is one question I should like to mention with regard to tuberculosis. It is the great difficulty in getting our clients to agree with us as to the valuation of milch cows. If the owner is not partly indemnified against loss, he will not report suspicious cases. You know perfectly well that owners having reported one case, take pretty good care they don't report another, for the compensation is so low. In view of the Pure Milk Bill mentioned in the House of Commons last night, it is the intention of the Board of Agriculture to deal with the

question by giving far better compensation, thus giving the owners some inducement to report if they wish to exterminate these cases.

Mr. CROWHURST: I had two cases, they complained that I had over-valued. One of the animals had just calved bringing up a calf and giving one and a half gallons of milk daily. The other had calved 7½ months, and in my valuation I took this fact into consideration. Considering the cow had gone seven months in calf again there was value attached to that compared with one that was empty. They reject that, however, and say it is not to be taken into consideration, only the butcher's value of the carcase, except in those cases where the animal is in such condition that we can take upon ourselves the responsibility of recommending it to be sold for human food. If you feel as I do in these cases you will take strong exception to recommending such animals for slaughter and sale for human food. My conscience will not allow me to recommend a portion of a carcase, with the diseased parts cut away, to be sold for human food. I think such would be pretty generally the opinion, as far as I know, of my brother professionals. I think this should be brought prominently before the County Council. Although we do this valuation, we have a conscience that requires satisfying. Supposing a farmer cut away the diseased portion and sent the rest to market, what position would he be in? Why should we occupy a different position to the owner? If the meat is sent to the butcher's and sold, the purchaser is only protected by the process of cooking the flesh.

Mr. DUNKIN: If the bronchial glands only were affected would you consider it fit for human food?

Mr. CROWHURST: If these glands were much affected I should not recommend it for human food. I cannot imagine anyone wanting to palm off a diseased carcase for human beings, and for it the public have to pay the same price as they would for good meat. If it was sent to the butchers he would get it at very much less than the normal value, but he would not dare to tell his customers that they could have it cheaper, because he did not pay so much for it owing to it being diseased; if he did so that customer would not go to his shop again, and it would do him serious injury. Therefore he has to charge the full price; and that applies to milk in the same way.

Mr. DUNKIN: You rather missed my point. Supposing any other gland were affected. There is the pharyngeal gland. Would you then pass the hind-quarters?

Mr. CROWHURST: I made it quite clear. I should refuse when lesions were distinct.

Mr. MORRIS: The Royal Commission I believe said the whole of the carcase in this condition should be passed.

Mr. COLEMAN: I should certainly not allow any part of the carcase to be used. If the peritoneum or pleura is affected the whole of the carcase should be destroyed. In all cases diseased parts have to be destroyed. I don't know that there is any note made of removing affected glands, although it is done in some parts. If I find the glands affected, the whole carcase is unfit for human food.

Referring to Mr. Crowhurst's remarks respecting valuation, I saw danger looming in the distance in the early stages of the Order, and on the 6th May last year in my district the question was mooted. I approached the Deputy Chief Constable, and through him pointed out that there would be great friction among the farmers if the veterinary surgeons had the valuation. We got them to agree to valuers being nominated for each division, and they had no instructions whatever as to the form of valuation, whether to inspect the animals for disease or health valuation. It was rather ambiguous. Sometimes an animal was valued at £22 if healthy,

and if diseased 30s. Now the valuers have to value them at health value, and if the value is £15 the diseased value will be £13. Supposing we have a cow valued at £13, and she is advanced tuberculous, he only gets £3 5s. of that £13, and if you value it at £6 as diseased he never gets more than the minimum, but the least value a valuer need ever put on any cow is £6. If emaciation is present, and there is one spot tubercular, it is looked upon as an advanced stage of tuberculosis, and the minimum price a valuer would put upon it would be £6. Many are sent to London and sold as meat.

The PRESIDENT: Our local authority at Margate will not permit the use of the meat of any animal that has been condemned for tuberculosis, and it is the burial of these carcasses which has led to correspondence between the Town Clerk and the Board of Agriculture. The Board said in their last letter that if they did not carry out the Order in its entirety, they would seriously consider about withdrawing their quota towards compensation. That would place the whole of the responsibility of compensation on the local authority, but they are most adamant. They say they are quite justified in their opinion, and will not permit the carcase of any animal I have condemned for tuberculosis to be used for human food, and they are all burnt in the usual manner.

Mr. CAUDWELL: With reference to the new Milk Bill; it will bring a largely increased number of tuberculous animals under the notice of the County Councils' inspectors. Compensation has been the crux of the whole thing. Farmers after being once bitten are twice shy. They hide their cases away and they fall into the hands of the cheap butchers, and we get fewer cases now than we did when the Order was first issued. The Board of Agriculture have promised increased compensation, and I hope it will be twice as much as the farmer is getting at the present moment, otherwise we shall not get any cases reported.

Mr. CROWHURST: What I want to impress upon you is that by accepting an office as valuer of tuberculous animals you have a very responsible post, and one by which, if we deal fairly with the public, we shall gain their esteem. If we recommend animals that are diseased to be sold for human food, we shall earn a reputation which will not do our profession much credit. A father of a family in a butcher's shop could not discriminate between one or the other. I should say the veterinary surgeon who passed such an animal was not acting *bona fide*, nor was he a credit to his profession.

Mr. WARREN: I endorse what Mr. Crowhurst says. I cannot think it can be right for any professional man to pass meat reacting to the tuberculin test. If you say it is localised, are you sure? I take it to be an infective disease. The ordinary inspector says "It looks a good carcase," but is everything discovered by that? It would be more to our credit if we said it showed signs of tuberculosis, and that in the interests of the public it should be destroyed.

I have had some rather peculiar experiences with regard to tuberculin tests. A little while ago I had 48 animals to test, and I did 24 one day and 24 the next. Of one batch no less than 18 reacted, and I believed it was unreliable tuberculin, and after three months the same 24 were tested again and only eight were wrong.

REPORT AND ACCOUNTS

For the twelve months ended 31st December, 1913, to be submitted to the sixteenth annual meeting of the members to be held at 10, Red Lion Square, London, by permission of the Council of the Royal College of Veterinary Surgeons, on Wednesday, the 3rd day of June, immediately after the annual meeting of the Royal College of Veterinary Surgeons, which takes place at 12 o'clock noon.

The Council begs to present its report for the year ending the 31st December, 1913.

The membership of the Society at 31st December, 1913, numbered 363, an increase of over 50 for the period.

The relief granted amounts to £350, which is a considerable increase over the previous year. During the past year weekly grants have been made in 18 cases. Three of the recipients were over 80 years of age (one of whom has since deceased), two widows are aged 60, and there are eight whose ages range from 51 to 58. One only, a younger woman, has "temporary employment," and she has seven children. Against all the other names is written "no income."

Increases have been made in grants in some cases where possible. Temporary grants have been made in five cases.

The Council desire to place on record the help given by Lady M'Fadyean in raising subscriptions to insure the retention of a son of a veterinary surgeon in a charitable school for a further period of twelve months.

The kind donation of £73 4s. 5d. from Mr. P. J. Simpson, of Maidenhead, the proceeds of an entertainment arranged by him, and further donations which have been received, have in accordance with Rule 4, been invested by the Trustees in Western Australia 3½ Stock 1920-35.

Christmas grants have been made to those widows who have children; in sums varying from £2 10s. to a widow with several children, to £1 in the case of small families, received principally from donations especially given in response to the President's appeal.

The Council present the balance sheet for the year, and desire to thank the Honorary Auditors for the work they have done, which must entail a great amount of time and labour.

ACCOUNT FOR THE YEAR ENDED DEC. 31ST, 1913.

JOSEPH WOODGER,
ALBERT E. LARK, F.C.A. } Hon. Auditors.

March 28, 1914.

WILLIAM SHIPLEY, Hon. Sec. & Treas.
28 Southtown, Gt. Yarmouth.

The Council note with regret the death of many old subscribers, and desire respectfully to recommend the favourable consideration of the Fund to the members of the profession when making charitable bequests.

The members are earnestly appealed to to use every means in their power to obtain new members, as it is only by this method that the objects of the Society can be attained. (A list of the present subscribers is annexed to the report).

The following members of the Council retire by rotation :—Messrs. Arnold Spicer, H. Sumner, Sir S. Stockman, R. C. Trigger, S. Villar, and S. Wharam; and they have been nominated for re-election. Professor Wooldridge has also been nominated, leaving one vacancy on the Council to be filled.

The auditors are Messrs. Joseph Woodger, M.R.C.V.S., and Albert E. Lark, F.C.A., who are recommended for re-election.

The Council fully recognise that the members of the profession cannot be aware of the distress that occurs amongst old members and also amongst the widows and children of veterinary surgeons who have died before they have made provision for their dependents. It must be apparent that no grant less than ten shillings per week can meet the pressing needs of a widow, even without little children. It is to be hoped that in future no grant should be less than that sum. This would entail at present an expenditure on grants alone of over £400 per annum, a sum quite impossible with our present income.

A subscription of 10/6 a year entitles to membership. The Council feels that, if every member of the Fund would endeavour to influence at least one other member of the profession, and point out the good work that is being done, our list should be doubled. The Secretary will be pleased to give any further information.

R. C. TRIGGER, President.

WM. SHIPLEY, Hon. Sec. & Treas.

28 Southtown, Great Yarmouth.
May 19th, 1914.

REPORT OF THE VETERINARY SURGEON TO THE CORPORATION OF THE CITY OF GLASGOW FOR 1913

[ABSTRACT.]

The number of home and foreign animals slaughtered and inspected was 427,449, of which 76,040 were cattle, 15,485 calves, 35,793 swine, 300,097 sheep, and 34 goats.

A comparison of the returns for 1913 with those for 1912 shows a decrease in the number of home animals slaughtered of 23,518 cattle, 23,084 sheep, and 14,697 swine; and an increase of 6,595 calves, and 14 goats. The number of foreign animals slaughtered shows a decrease of 663 cattle, and an increase of 501 sheep.

The most frequent disease affecting home animals is Tuberculosis. Following the precedent of former years, I submit statistics regarding its prevalence :—

*Percentage affected in Home and Foreign Animals Slaughtered at all the Abattoirs,
and Results of Adjudication.*

	Slaughtered.	Affected.	Destroyed, totally.	Partially.	Passed.
		Per cent.	Per cent.	Per cent.	Per cent.
Home Cattle	76,040	8,647 11·37	969 11·20	852 9·85	6,826 78·94
„ Calves	15,485	42 27	19 45·23	3 7·14	20 47·61
„ Swine	35,793	1,986 5·54	64 3·22	14 70	1,908 96·07

*Comparison between Tuberculosis and Non-Tubercular Diseases in Carcases of
Home Animals dressed in Glasgow during the Year 1913.*

		Oxen.	Bulls.	Cows.	Heifers.	Calves.	Total.	Swine.	Sheep.	Goats.	Total.
Tubercular	Total	57	20	873	19	19	988	64	1052
	Partial	194	72	544	42	3	855	14	869
Non-Tubercular	Total	70	10	745	17	215	1057	97	296	...	1450
	Partial	72	12	126	8	5	223	74	70	1	368

THE SLAUGHTER OF CALVES.

During the year under review 15,485 calves were brought to the city abattoirs. This number is 6,595 in excess of that for 1912.

In years past it was the custom for farmers to slaughter their calves and to consign the carcasses to a trader in the city. Now many traders located in the city travel the country, purchase from the farmer and bring the live calf for slaughter to one of the abattoirs. The veal from such calves is in better condition, so that this change of policy is to the benefit of the consumer as well as the trader. A very considerable number of carcasses is still being consigned from outlying districts, and many of these carcasses have to be seized on account of bad handling.

The age of the majority of calves placed on the Glasgow market as veal varies from one to seven days. Veal prepared from such immature calves has been used as an article of human food for ages, but it cannot be considered as of good dietetic value. Apart altogether from this question the ruthless slaughter of calves ought to be restricted. It is perfectly true that many calves are not suitable to be kept for stores, but others are, and in the course of time would augment our ever-diminishing supply of home-fed beef.

MILK SUPERVISION.

It must be candidly admitted that the public, who are certainly the chief sufferers from an impure milk supply, are also the chief offenders, because, owing to their crass indifference and craze for the "big pennyworth," they encourage falsification and slovenly habits. It cannot be too strongly emphasised that pure milk is an invaluable food, whilst impure milk is a virulent poison. The public must recognise that it is necessary for them to pay more for their milk—in other words, to produce a high-grade quality of milk entails increased cost of production.

It is common knowledge that much of the milk sold in this city at the present time is unfit for human consumption. To put it bluntly, it is *not* milk, but a mixture of milk and filth. I grant that this is a strong statement to incorporate in an official report, but the circumstances demand it. Day by day the evidence is accumulating to show that the danger to man from an impure milk supply has not been over-estimated but underrated, and if the present slaughter of the innocents is to be stayed, strong measures must be taken.

The efforts made by the authorities of Geneva—a city in the State of New York, with a population of, in

round number, 13,000—is worthy of our serious consideration. In 1907 the milk supply—the produce of 550 cows—was in the hands of 40 dairymen. The conditions under which the milk was produced, handled, and sold were perhaps no worse than those which at present obtain in every town and city in the United Kingdom. Through the influence of the then Mayor, A. P. Rose, Esq., an inspector was appointed, and a systematic inspection was inaugurated of all dairies supplying milk to the city. The conditions found were recorded on the score card devised by Prof. R. A. Pearson, of Cornell University, which provides for a maximum score of 500 allotted equally between (1) health of the herd and its protection, (2) cleanliness of the cows and their surroundings, (3) construction and care of utensils, (4) health of employees and manner of milking, and (5) handling the milk.

If the total of all scores is :	and each division is :	the sanitary conditions are :
480 or above,	90 or above	Excellent.
450 „	80 „	Good.
400 „	60 „	Medium.
Below this standard		Poor.

The Board of Health convened a meeting of the dairymen, and explained to them the object of inspection. The Board intimated that they did not intend to employ coercive measures, but, after the expiry of a reasonable time, they would publish the scores of every dairy of supply, and thus enable the public to use discrimination in the purchase of milk.

Each producer was furnished with a duplicate of the score card in order that he might be made acquainted with the defects found; special attention being directed to those which could be remedied at little expense. At the same time he was requested to lodge objection to any error in scoring.

The first inspection was made during the months of September and October, 1907, with the result that 5 per cent. of the dairies were classed as "good," 57·5 per cent. as "medium," and 37·5 per cent. as "poor."

At the end of 1910, 12·8 per cent. were classed as "excellent," 74·4 per cent. as "good," and 12·8 per cent. as "medium."

The scores of the first quarter of 1911 showed that 12·8 per cent. were "excellent," and 87·2 per cent. as "good."

The Board in 1908 decided to make public the scores of the dairies of supply. Against this decision a few

dairymen—who had not taken the earlier statements of the Board seriously, and had made no effort to improve the condition of their dairies—lodged a protest. A meeting was arranged, and the points of difference were freely discussed. The opposition of the few who were not prepared for publication was outweighed by the approval of the many who stated that they had striven hard to merit a good score, and now publicity was due them and they demanded it. Accordingly, the scores were published in the press; under each distributing dairy being grouped its contributing dairy farms with their respective classification. The attention of the public was at the same time called to the fact that the milk offered by any retailer was no more desirable than that of his poorest producer, since if he mixed the milk from all of the dairies it would be all reduced to the level, and if he did not mix it someone would get only the poorest milk.

Prior to 1st April, 1909, the milk was distributed through the agency of a company and nine private traders, but on that date the latter combined and formed what will hereafter be designated the "New Company."

The management of the old company undertook to pay the producer on a scale for graded milk. The official score of the dairy for each quarter was to be taken as the basis for making settlements. The new dairy company did not have such a clause in its contracts.

It is of great interest to note the effect of this policy. Of the nine dairies supplying milk to the old company, three were classed as "excellent," and six as "good," with an average score of 474 marks. Of the twenty-five dairies under contract with the new company none were "excellent," fifteen were "good," and ten were "medium," with an average score of 453 marks. The former not only maintained the improvement, but gained a higher average score. On the other hand, the latter showed a decided retrograde movement. In one case a score of 476 marks in March fell to 454 marks in June.

The trade of the new company decreased, whilst that of the old company increased. As the milk was sold at the same rate by both companies, it is reasonable to deduce that the more enlightened portion of the community patronised the vendors who could produce the more satisfactory evidence that the milk sold by them was produced and handled in a proper manner.

It is true that the difficulties to be overcome are many in adopting such a method to control the milk supply of a great and populous centre such as is Glasgow, but if a few of the more enterprising dairymen were to agree it would certainly exert a powerful stimulus on the whole trade.

The amount of capital at first invested was only about £550, but, owing to the enormous demand for the supply of milk, this sum had to be augmented, and it now stands at £8,250. The actual assets of the Company, however, are returned at £27,600.

At present there are forty farms, representing 5,000 cows, supplying milk to the Company. Briefly put, the lines upon which the Company works is tersely expressed in their motto, "Clean milk from healthy cows," and in endeavouring to realise this high ideal they insist on all milk sold being in conformity with the following requirements:—

- (1) The cows must be periodically examined by veterinary surgeons, and only those found healthy retained in the milking herd;
- (2) The conditions of the contract, which have for their object the minimising of the risk of extraneous contamination, must be strictly observed; and
- (3) The milk must at all times be kept at a low temperature, so that the growth of fermentative and putrefactive organisms which have gained access is inhibited.

The conditions of contract regulate not only the sanitary conditions under which the cows are housed, the grooming of the cows, the cleanly condition of the milkers, the storage of dairy utensils, and the milk itself, but also stipulate that the food of the cattle be in a thoroughly wholesome condition of good quality, and free from substances capable of imparting an unusual flavour to the milk.

The Company sells its produce at the undernoted prices per gallon:—Whipped cream about 5s.; Cream 4s. and 3s.; Whole milk 10d.; Skimmed milk 5d.; Milk for children 1s.; Milk for babies (modified and pasteurised), about 1s. 6d. to 2s. 3d. (according to proportions of water and sugar); Butter milk, about 6d.; Cruets about 4½d. to 6d. each.

Prior to the establishment of this Company the milk supply of Copenhagen was unsatisfactory. For example, of 111 samples of cream taken during the months of August and September, 1876, only 2 were found to be of good quality, while 24 had been adulterated with starch in the proportion of 6 to 11 per cent. To-day it is universally regarded that the milk supply of Copenhagen is second to none in the whole civilised world.

[Mr. Trotter here cites the finding of the Royal Commission (second interim report) on tuberculous milk, and the results recently published by Dr. Mitchell].

INSPECTION OF MILCH COWS.

City. From 1st January to 23rd October, the cowsheds in the city were visited by a veterinary inspector from this Department on 690 occasions, and the milch cows housed therein were examined, with the result that 154 were found affected. These were dealt with as follows:—

14 Systemic,	Milk destroyed.
8 Mastitis, Acute,	"
116 " Chronic,	"
16 Prominent Lymph. Glands,	"

Country. Farms situated outside the city were visited on 488 occasions, and 12,480 milch cows were examined. 221 were found affected, and dealt with as follows:—

18 Systemic,	Milk destroyed.
183 Mastitis, Chronic,	"
20 Prominent Lymph. Glands,	"

FEVER HOSPITALS' MILK SUPPLY.

The farms supplying the fever hospitals with milk were visited on 79 occasions. By the terms of contract the farmers undertake "that no milch cow shall be added to, or retained in, the herd if . . . it reacts to the tuberculin test."

Tested.	Negative.	Positive.	Doubtful.	Rejected.
161	84	60	17	77

In addition to being tested with tuberculin, the cows in these herds are clinically inspected at frequent intervals. On these occasions 37 samples of milk were drawn from cows showing abnormal changes in the udder, and one swab was taken from a cow with a mucopurulent discharge from the lungs. These samples and swab were submitted to the bacteriologist, who, after inoculation experiments, reported that they were not infected by tubercle bacilli. The farmers, too, are under contract to immediately notify all cases of illness occurring among their cows, and to isolate all those affected.

LABORATORY.

For meat and milk inspection a laboratory is indispensable. Since this Department was organised it has been the custom to examine the blood or tissues of every animal brought to the abattoir dead or in a dying condition, as well as every suspicious carcase consigned

outwith the city boundaries to traders. Of such, 588 were microscopically examined during the period under review. For some time past I have been of the opinion that better methods could be adopted, and with this object in view a series of experiments have been carried out. So far the results obtained have been extremely gratifying, and warrant these researches being continued. I trust that I shall be able to report more fully on this method in another year.

On several occasions flies caught in the abattoir were made to walk over gelatine plates. The result showed that many were grossly contaminated with organisms. There is no question but that these pests may, and do, contaminate food, and an organised effort ought to be made to eradicate them.

VETERINARY ATTENDANCE ON HORSES.

The examination of horses belonging to Health and Sanitary Departments as to soundness or illness necessitated 21 visits during the year.

A. M. TROTTER.

A Disputed Account.

Before his honour Sir W. Lucius Selfe, in the West London County Court, William Sewell, veterinary surgeon, of South Kensington, sued Miss Victoria Monks, music hall artist, for £24 fees for attendance on a pet dog.

In his evidence, plaintiff said, in answer to a telephone message, he attended at the defendant's flat in Acacia Road, Maida Vale, on Dec. 1 last, and was asked to treat a pet terrier by the defendant. He found it to be suffering from pneumonia, which subsequently developed into distemper. He treated the animal, attending daily till the 24th, when it had recovered. He sent in his bill in January, but it was returned through the dead letter office.

Mr. W. H. Lever: You could have had no difficulty in finding the defendant, she is a well-known music-hall artist?

Plaintiff: I never heard her name before this.

You charge a guinea a visit. Can you show me any other client to whom you made this charge?

Plaintiff quoted Mr. Albert Chevalier.

Mr. Lever asserted that the charges were exorbitant. The plaintiff was then required to produce his ledger, and Mr. Lever went through the pages. Counsel remarked that 3s. 6d. seemed to be the usual charge to other clients, but in regard to the account against the defendant the plaintiff had charged for December 4, one guinea for a visit, also £1 11s. 6d. for a second visit, taxicab 5s., medicine 2s. 6d.; something like £4 for a single day.

Plaintiff: I was called in the forenoon and again at 7.30 p.m., for which 10s. 6d. extra is charged. He added that he saw the defendant in the dining-room, five or six times, and she told him the dog was hers.

Miss Monks said the dog, a small Yorkshire terrier, was originally hers. It was seven years old, and she gave it to Mrs. Dunville many months ago. She denied that she had telephoned for the plaintiff to attend the dog, asserting that she had never had any conversation with him about the dog at any time; the attendance on the dog was entirely Mrs. Dunville's affair. Miss Monks added that though she was not liable, she would have paid for her friend, but for the fact that the plaintiff's charges were so extravagant.

Mr. Lever: Why are you resisting this claim?

Defendant: It is so exorbitant—a guinea a visit is beyond all reason! I am quite willing to pay something for the dog's sake, but not these charges.

A veterinary surgeon stated that the plaintiff's

charges were very high. Five shillings or 7s. 6d. a visit would be fair, and most "vets" would charge 3s. 6d.

His Honour said he did not think the defendant was liable, but she had intimated she would consent to judgment for a reasonable sum. This was a monstrous account; he had never seen anything like it in his life. He had paid doctor's bills, veterinary's bills, and other bills but this one beat the record. The amount for a visit would be high at 10s. 6d. If the defendant was willing to pay an amount for this dog he would fix it at £10 6s. 5d.

Mr. Lever: I trust your honour will not enter this as a judgment against Miss Monks. She will be extremely pleased to pay whatever amount your honour thinks fair. She is quite ready to pay, but not under the threat of legal proceedings.

His Honour: There will be judgment without costs for the defendant, on her undertaking to pay that amount.

Mr. Lever: That will be satisfactory.

Neglect of Pit Ponies.

Evidence of ill-treatment of pit ponies was heard at Nottingham on 27th ult. Fines totalling £64 were inflicted on the Digby Colliery Company, Mr. T. Dennis Bayley, J.P., managing director, and Mr. Raymond Nadin, manager, for not exercising supervision over horsekeepers, allowing an unqualified man to act as deputy, not providing sufficient room for ponies to work in without their rubbing on the roofs, and not providing refuge holes on haulage roads. A mines inspector stated that ponies 4ft. 6in. high were working in places where the roof was only 4ft. 2in. high. A large number were working with big, raw sores, many of at least months' standing.—*Evening Express* (Neath).

Personal.

Mr. WILLIAM WALTERS, M.R.C.V.S., Abersychan, Mon., will act as judge of Colliery Horses at the Welsh National Show to be held at Newport, Mon., on July 21—23.

Mr. A. POTTIE, jun., M.R.C.V.S., Paisley, was one of the judges of the Light Horse Class at the annual show of the Erskine and Inchinnan Agricultural Society, held on Tuesday, June 2nd, at Kingston, Bishopston.

Mr. W. LOGAN, M.R.C.V.S., Inverness, will act as judge of the Roadsters (driving and leaping) at the annual show of the Royal Northern Agricultural Society to be held at Aberdeen on Thursday, July 23rd.

Mr. W. F. HOUSTON, M.R.C.V.S., Paisley, acted as judge of the Light-legged Horse class at the sixty-third annual show of the Cambuslang, Blantyre, and Rutherglen Agricultural Society, which was held at Westburn, Cambuslang, on Saturday, May 23rd.

Mr. A. POTTIE, jun., M.R.C.V.S., Paisley, was one of the judges of the Light Horse class at the Largs, Cumbræ, and Wemyss Bay Agricultural Society's annual show at Glenacre, Largs, on Saturday, May 23rd.

At a meeting of the Executive Committee of the Aberdeen County Council on Friday, May 22nd, several appointments of veterinary surgeons were made:—

Mr. GEORGE J. S. MOWER, M.R.C.V.S., was appointed veterinary inspector for the parishes of Auchindoir, Rhynie, and Clatt, in room of the late Mr. Morrison.

Mr. WILLIAM S. LORNE, M.R.C.V.S., was appointed for the parish of Turriff and part of Monquhitter.

Mr. WILLIAM MARSHALL, M.R.C.V.S., following upon his appointment under the Aberdeen Town Council, resigned his position as inspector for the parishes of Newhills and Oldmachar. He recommended for the position,

Mr. ROBERT E. DRENNAN, M.R.C.V.S., who was unanimously appointed.

OBITUARY

HENRY HILLS, M.R.C.V.S., Cambridge.

Graduated, Lond: 1864.

Mr. Hills died on May 22nd, aged 70 years. The funeral took place at St. Andrew's, Old Chesterton, on Monday afternoon. The chief mourners were Mr. E. Hills (brother), Mrs. Reeve (sister), Mr. Reeve, Miss Fisher, Mrs. Pooley, Miss Harvey, Miss Bavey, and Mr. Robinson. There were many floral tributes from relatives and friends.

HUGH FERGUSON, M.R.C.V.S., Warrington.

Edin: April, 1870

Death occurred on May 29th from cerebral degeneration, at the age of 68.

DEAN.—On the 30th May, at 22 Rubislaw Den, North Aberdeen, George Dean, M.A., M.B., C.M., Regius Professor of Pathology in the University of Dublin.

[Prof. Dean was an Examiner for the Diploma of Membership R.C.V.S. in 1900-01].

NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

Sir,

However wrong Mr. Toope may consider I am in my deductions as to his attitude towards this Association, it is preposterous for him to say that I misquoted him, or rather that I wilfully omitted a portion of his remarks in order to distort his meaning. Here are his exact words as reported in your columns:

The President: "Do you not think that is rather clashing with the National Veterinary Inspectors?"

Mr. Toope "Did not think so at all. The idea seemed pretty general that the National Veterinary Inspectors were practically non est. Nothing appeared to have been done by them."

I find, on reference to the report, that the words underlined were omitted from my quotation, but this was done quite unconsciously on my part and, in any event, I do not see that the omission alters Mr. Toope's meaning in any substantial degree. The words added by Mr. Toope in his letter of May 30th do not appear in the original account of the meeting, so that if he was wrongly reported the fault is not mine.

But the "real object" of my previous letter was to induce Mr. Toope to come out into the open in order that we might learn the reason for his notorious disregard of the existence of this Association in his advocacy of small sectional societies. In this, I think, I can claim to have been successful, for Mr. Toope, as showing his interest in the concern, has now replaced his policy of ignoring the Association, or advertising its supposed non-existence, by a more straightforward one in which he deplures that "it was ever born."

He has not hitherto given public expression of his opinion, but I think I can show that he has probably held it since the commencement. Speaking at the Holborn Restaurant on April 7th, 1913, Mr. Toope said "he thought there was no necessity for the formation of a National Association of Veterinary Inspectors, and he had drawn up a scheme which he intended to present on the following Wednesday to the Southern branch of the National Association, whereby all those present could be taken in and made members of the National without causing any possible split in the ranks of the profession." This he embodied in a proposition which was subsequently withdrawn on an agreement being arrived at by which the two Societies were to be affiliated. Ever since that time, so far as one can judge from the reports published, he has consistently ignored the existence of this Association in his advocacy of local inspectors societies, and I owe him an apology if from this, and other evidence in my possession, I have wrongly diagnosed the case as one in which "the wish is father to the thought."

The statement that the formation of this Society immediately led to the reduction of fees paid by the Kent County Council to the tune of 33 per cent. is absurd on the face of it, but even if it were true this one case of "levelling down" is more than counter-balanced by the "levelling up" on the part of many local authorities who have adopted the scale almost exactly as suggested by the Association. But this question of "levelling down" does not arise, for the reason that the only branch of inspectors' work which the Society has so far tackled is that in connection with the Tuberculosis Order, and as no fees for this work were payable prior to the formation of the Society, how could its origin have led to their reduction?

Further, if the mere preparation of a scale of suggested fees with a declared non-militant policy is to lead to a 33 per cent. reduction, what good is likely to come of Mr. Toope's efforts to collect, tabulate, and agitate for an increase of the fees commonly paid for some other kinds of veterinary work, especially when this demand for increase is accompanied by a threat that those not accepting the revised scale may expect to be boycotted (*The Veterinary Record*, May 23rd, p. 763).

Everybody knows that no local authority (or anyone else for that matter) can be forced to adopt any particular scale of fees, the preparation of which was never undertaken by the Society with this object. We simply desired to place in members' hands a suggested scale with which, if invited to do so, they could approach their local authorities, or which might be of some service and support to them in their efforts to obtain adequate remuneration for very responsible work. If the list of suggested fees has been used in any way other than that intended, if, that is to say, it has been put forward in the nature of a demand, the authorities would naturally resent the impropriety and, in this event, a 33 per cent. reduction, in my opinion, would be all too small in comparison with the amount of tact displayed. Will Mr. Toope tell us in what other way this levelling down of the fees paid by the Kent authorities has resulted for anything this Association has done.—Your obedient servant,

TREVOR F. SPENCER, Hon. Sec.

Kettering, June 2nd.

A CORRECTION.

Sir,

I should be pleased if you would note a slight correction in your report of the discussion at the meeting of the Midland Counties V.M.A. What I stated in speaking of an outbreak of foot-and-mouth disease was, that I had since seen animals with very similar lesions in the mouths and on the coronets, and also shaking their feet, but had never since noticed the peculiar smacking sounds referred to by Mr. Trigger.—Yours faithfully,

A. B. FORSYTH.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1353.

JUNE 13, 1914.

VOL. XXVI.

THE INTERNATIONAL VETERINARY CONGRESS.

The arrangements for this Congress are now far advanced, and everything augurs success. The donation list still remains open, but enough has been collected to remove all fear of financial difficulties. Ample support—as much, indeed, as any British Government could be expected to give to a professional Congress—is being accorded by the State. The King has graciously consented to become the Patron of the Congress. The President of the Board of Agriculture is Chairman of a powerful Honorary Committee, which also includes the Lord Mayor of London, and the Ambassadors, Envoys, and Plenipotentiaries of the various countries represented at the gathering. Apart from the serious work of the Congress, a most attractive social programme has been prepared, full details of which will shortly be announced.

One other thing is now necessary to ensure a completely successful Congress, and that is a good attendance of members from the British Islands. A record attendance of foreigners is expected, but they will not be favourably impressed with our national *esprit de corps* if only a few of us assemble to meet them. In that case there might be a partial failure, which a good attendance will avert.

We have many other reasons for attending this Congress. Many of us cannot well attend it abroad, but most can here, and as it is not likely to meet again in England for many years, this is the chance of a lifetime to some. The time of year is as convenient as any for a holiday, and there are special travelling facilities. The railway companies will grant return tickets on excursion terms to members in Great Britain on the production of vouchers.

Members are therefore urged to attend the Congress and bring their lady relatives, registering the latter as external members. The fee for this—the “lady’s subscription” is only five shillings—and only such ladies as are so registered will be admissible to the evening functions.

All the Governments whose veterinarians take part in the Congress are encouraging it through their diplomatic representatives in London. Our Government is doing as much for it as our national usage permits. And we veterinary surgeons in Great Britain and Ireland have already done more than veterinary surgeons abroad are ever required to do—we have succeeded in financing the Congress. Having done that, we must not fail to crown our success by a good attendance.

SARCOMA OF LIVER AND SPLEEN IN DOG.

The subject of the following case, a small sized Airedale terrier dog, was brought to me for treatment at the Government Dispensary, Nairobi, some time ago.

On casual examination one could observe marked distention of the abdomen, and ascites was suspected. But on palpation it soon became evident that the great enlargement of the cavity was due, not to dropsical fluid but to a large firm mass which was quite readily detected through the abdominal wall, and a tumour was diagnosed.

The mucous membranes were yellow, bowels constipated, and the appetite in complete abeyance. The animal was in an extremely weak and emaciated condition, which only tended to show up more clearly the pendulous and enormously distended abdomen.

According to the history as furnished by the qualified Indian Veterinary Assistant at the Dispensary, this animal had been brought at frequent intervals for treatment during the last twelve months for congestion of the liver and indigestion, and it was only during the last month that the abdomen was noticed getting gradually larger and more pendulous, and that ascites was suspected.

The appetite had never been too good, and the bowels were always more or less constipated.

As the prospects of a successful operation were remote, the painless destruction of the animal was advised, and to this course the owner reluctantly decided.

In order to satisfy myself that the condition was really hopeless, and that no permanent relief could be given, I prepared the site of incision and chloroformed the animal as for operation.

On opening into the cavity a large amount of blood-tinged serum escaped, roughly two pints. The incision being continued the spleen, enormously enlarged and nodulated on its surface, came to view, and so finally decided the destruction of the animal.

After death the cavity was laid open, and revealed the marked alteration in structure of the liver and spleen, as nearly the whole normal tissue of these organs was replaced by tumour tissue. Even the epiploon was invaded by myriads of small tumour-like bodies, evidently immature forms of the same neoplasm formation.

The liver and spleen weighed respectively 6½ and 2 lbs.

On a piece of liver and spleen being submitted to Mr. R. E. Montgomery, Veterinary Pathologist,

for examination, he gave it as his opinion that the tumour formation was mixed celled sarcoma.

The rarity of the condition and the opportunity afforded of presenting the excellent photographs, which were taken at the time by Mr. R. J. Stordy, Chief Veterinary Officer, and which so clearly show up the lesions found on post-mortem, are the reasons for publishing the case.

W. W. HENDERSON, M.R.C.V.S., D.V.S.M. (Vict.)
Veterinary Officer.

Nairobi, B.E.A.

HYSTERIA IN A MARE,

Subject. A twelve-year-old Hackney mare with foal at foot, bred by the owner, had had four previous foals.

History. The mare was served on Thursday evening last, by a well known hackney stallion, the sire of all her previous foals, and the service seemed quite satisfactory. However, the stud groom advised the owner that she should be left at the stud overnight and be put to the horse again on the following morning. Early on Friday morning it was noticed that something was wrong, and assistance was sent for.

Symptoms. The animal was found to be very uneasy and apparently suffering great pain. The head was stretched out and the tail highly elevated. All the muscles of the frame were hard and tense, and the least excitement set them into tonic contractions. She grated her teeth persistently, and saliva ran freely from the mouth, as there appeared to be some difficulty in swallowing. An examination of the vagina revealed a highly congested condition of the mucous membrane, and the labia of the vulva were constantly opening and closing, each movement being attended by a desire to micturate. Now and again a small quantity of thick whitish urine would be ejected. The pulse was quick and irritable,

Treatment. She was put into a dark, quiet loose box with her foal, and given a liberal supply of water. No attempt to administer any medicinal agent was thought of, owing to the state of excitement of the animal when handled.

When again visited in the evening most of the urgent symptoms had passed off, although the grating of the teeth still persisted. On Saturday morning she was practically well again, and had begun to eat a little, and since then has shown no further signs of any excitement.

It is of interest to know that the mother of this mare, also the property of the above owner, exhibited similar symptoms two years ago, after being served by the same horse.

GOVERNMENT PUBLICATIONS.—Messrs. Wyman and Sons, Ltd., official sale agents in England and Wales for Parliamentary papers and Stationery Office publications have issued the following, post free. Board of Agriculture, Report of the Chief Veterinary Officer for 1913 price 3½d.

FATAL POISONING BY THE EXTERNAL APPLICATION OF OIL OF TAR.

The subject of this case was a black pony, aged about eight years, and about 14 hands high. The owner noticed two or three bare spots on the skin, and fearing lest the cause of these might be mange he decided to dress the animal all over with train oil. By mistake, however, *oil of tar was used instead of train oil*. The owner dressed the pony all over with the oil of tar, using in all about three pints. This was done at about 6 p.m. On his return to the stable at 7 p.m. the pony was found to be in great pain and blowing badly; it soon after fell down and was unable to rise again. I was sent for and saw the pony at about 8.30 p.m. The animal was then lying on its off side, all four limbs were stretched out and quite rigid, jaws tightly clenched, pulse imperceptible at submaxillary artery, there were frequent twitchings of the muscles of the trunk, consciousness was quite lost, no response being shown to the corneal reflex test.

Prognosis, naturally, was very unfavourable. I had the whole of the body well washed with soap and water, and then douched with cold water. Emollients were applied to the skin, stimulants given, and the pony then well covered with loose straw. Death, however, occurred in about three hours.

No doubt the poisoning was due to crude carbolic acid contained in the oil of tar. The chief points of interest in the case to my mind are:

1. The remarkably rapid progress of the poisoning.
2. The fact that there is sufficient acid in oil of tar to kill a horse in a few hours when applied to the skin in its crude state.

RALPH BENNETT, F.R.C.V.S.

Romford.

ABSTRACTS FROM FOREIGN JOURNALS

EQUINE EPIZOOTIC ABORTION.

K. F. Meyer and Fred Boerner report (*The Journal of Medical Research*, 1913) the results of their investigation of an outbreak of epizootic abortion amongst horses in Pennsylvania. They found the cause of the outbreak to be a bacillus belonging to the sub-group C. of the paratyphoid-enteritis group. They propose the name of *Bacillus abortus equi* for this organism.

This bacillus possesses all the properties of the bacteria that are classed in the paratyphoid B group: but can be distinguished from them by possessing the two properties of forming membranous, dry, brittle deposits on sloping agar, and of ability to produce a considerable gas-formation in sugar. The *B. abortus equi* is only agglutinated by a paratyphoid B. serum or an enteritis serum in low dilution.

The authors found that abortion could be produced with cultures introduced subcutaneously,

intravenously, and intravaginally, and also by feeding, in a variety of animals, viz., one cow, one goat, one sow, and rabbits and guinea-pigs. The average period of incubation was fifteen days. The abortion bacillus of the horse is pathogenic for guinea-pigs, rabbits, mice, rats, and pigeons. The anatomical lesions resemble those of a paratyphoid infection. Rabbits are more susceptible than guinea-pigs.

Agglutination and complement-fixation can be regarded as useful methods in establishing an infection with the bacillus. Further investigations are required to explain the method of natural infection.—(*Berliner Tier. Woch.*)

EQUINE MUSCULAR RHEUMATISM COMPLICATED WITH PETECHIAL FEVER AND ENDOCARDITIS.

Prof. Fröhner records (*Monatshefte für Prakt. Tierheilkunde*) this case of a horse. At the beginning of the illness the symptoms were vague, but after a few days one fore fetlock joint suddenly showed inflammation without demonstrable cause, the other fore fetlock followed suit two days later, and the diagnosis of articular rheumatism could be made. Hyperleucocytosis and considerable cardiac weakness were also present. The next day the right knee joint also became inflamed. Treatment by aspirin was instituted, and was followed by a reduction of the temperature, but the pulse rate remained high, and finally the appetite was destroyed. On the latter account sodium salicylate was then given *rectally* to the amount of 100 grammes (= approximately 3½ oz.) daily, with better results. The cardiac weakness and the tachycardia, however, still persisted. A few days later numerous petechiæ, ranging up to the size of a millet seed, appeared in the anterior part of the nasal mucous membrane. The pulse rate had risen to 100, but the sounds of the heart were still clear, without accessory sounds. The horse received petechial fever serum. Improvement now set in, and the inflammations of the joints disappeared. Suddenly, however, the horse died of cardiac paralysis. Post-mortem, an ulcerous endocarditis was found on the tricuspid valves, and a chronic fibrous endocarditis on the bicuspid valves, together with dilatation of the heart, blood stasis in the lungs, and pulmonary œdema.—(*Berliner Tier. Woch.*)

SEPTICEMIA IN CALVES FROM THE MEAT INSPECTOR'S POINT OF VIEW.

Luxwolda describes (*Tydschrift voor Veeartsenij-kunde*) the lesions which he observed in 62 calves affected with septicæmia. He arrives at the following conclusions:

The meat may be considered wholesome when the flesh and the intermuscular lymphatic glands contain coli bacteria, provided that the flesh has not a disagreeable odour and that the number of bacteria is not too considerable. The meat should be condemned when it contains paratyphoid bacilli, as they belong to the group of *bact. Gartner* or to the paratyphoid B. group. In this connection the author shares the views of Bugge and Franke.

Other authors, Iunack in particular, think that only meat containing *bact. Gartner* should be condemned, because these germs produce toxins which resist boiling, while boiling renders the paratyphoid B. organisms inoffensive. Although this view may be sustained theoretically, the author nevertheless thinks that it might be dangerous to put it into practice. It should be remembered that the distinction between these two groups of germs can only be established by agglutination tests, which necessitate a good deal of time. Moreover, their toxic power and pathogeny for man and animals, as well as the particular conditions which modify that power, are as yet very little known. The author also thinks that there is a difference between the *Gartner* bacilli of the septicæmia of calves and the *Gartner* bacilli which are pathogenic to man, the first-named having little or no pathogeny for human beings. Up to the present, it is unknown whether there are any special influences capable of augmenting the toxicity of these bacilli for man, but it may be considered as certain that the agents capable of causing these flesh-intoxications are very variable and adapt themselves with facility to the media of different animals. In any case, the author thinks that it is necessary to be extremely prudent in the examination of calves affected with septicæmic conditions. A minute bacteriological examination alone permits a sound judgment to be formed.—*Annales de Méd. Vét.*

THE EVOLUTION OF THE HYPODERMA BOVIS.

Adrien Lucet, of the Laboratory of Comparative Pathology at the Paris Museum, reports (*R. C. Ac. des Sciences*) the result of investigations he has made into this question. The *Hypoderma bovis* causes enormous losses to agriculture by the damage it causes to the skins of cattle alone. The author's conclusions, commencing a survey of the life-cycle at the moment when the larva leaves the subcutaneous nodule it has formed, are as follows:—

1. In our climate (presumably the French climate—*Transl.*) the larvæ quit their subcutaneous refuge in May, June, and July.
2. The larvæ fall upon the ground, remain there at its surface, and are transformed into pupæ in from twenty-four to thirty-six hours.
3. The average duration of nymphosis is from thirty to thirty-five days.
4. The hatching of the perfect fly takes place at all hours of the day—not in the morning only, as is asserted in Germany. Hatching is accomplished in a few minutes, and the insect is ready to fly.
5. Among the enemies of the larvæ are small rodents, birds, insects, and even certain fungi (notably *Mucor*), which penetrate through the chitinous integument, vegetate upon the chrysalides, and destroy them.
6. It is easy to rear the larvæ in the laboratory at the ordinary temperature, either upon grass, or more particularly, upon a layer of cotton wool.
7. The fly is only encountered from the middle of June to the beginning of September. The average duration of its life is only from four to five days.

8. The eggs, which average 360 in number, are deposited by the female upon the surface of the skin and upon the hairs, to which they adhere.

9. The larvæ may easily be killed by once or twice injecting $\frac{1}{2}$ c.c. or 1 c.c., of pure or diluted tincture of iodine into the parasitic nodules. Resorption takes place rapidly.—*Annales de Méd. Vét.*

POISONING BY OLEANDER LEAVES IN THE HORSE.

Leicht, of Isen, records the case of an eight-year-old heavy draught horse which, while waiting in front of a tavern, ate some oleander leaves growing near. The next day the animal showed loss of appetite, cerebral depression, and violent diarrhoea. The respirations were frequent and deep. The pulse was irregular and uneven, and counted 60 to the minute. The rectal temperature was 102.2° F. The day afterwards the condition grew worse. The pulse became almost imperceptible, the horse trembled violently upon the fore extremities, and there was frequent straining to defecate and urinate. The rectal temperature was now 104.5° F., the respirations were very frequent, peristalsis was very lively, the abdomen showed a moderate degree of tympany, and the mucous membranes of the head were bright red. Death took place forty-eight hours after the oleander leaves were eaten. The author says nothing of any post-mortem examination, and does not indicate the treatment he adopted.—*Munch. Tier. Woch.*

W. R. C.

SARCOSPORIDIN

Is the name of a toxin derived from sarcosporidia (*Sarcocystis tenella*) possessing lethal qualities for sheep, goats, and rabbits, white rats and sparrows. It produces paralytic symptoms and anaphylactic shock. In rabbits progressive doses result in immunisation, but of short duration.—*Cent. f. Bakt.*

F. E. P.

ANTI-ABORTION VACCINE EXPERIMENTS.

The results of a number of important epizootic abortion experiments which have been carried out in Oxfordshire were embodied in an interesting report presented to the Education Committee of the County Council. The report has been prepared by Mr. G. R. Bland (Staff Instructor in Agriculture), and deals with experiments carried out in 14 herds during the period 1911 to 1913.

The report points out at the outset that Oxfordshire is every year becoming more and more important as a milk-producing county. The extent of the industry may be realised when it is considered that in the year 1911 there were, according to the returns of the Board of Agriculture and Fisheries, 23,824 cows and heifers in the county; 16,390 of these animals were in milk. Supposing that the average annual yield of each cow in Oxfordshire is 550 gallons, there was produced in the year 1911 a total yield of 9,014,500 gallons. This quantity, valued at 8d. gallon, was worth no less than £300,483. Owing to the prevalence of "contagious abortion" and to the many requests for advice received as to the best methods to adopt for its prevention and eradication from herds, it had for a long time been felt

that some carefully conducted trials of different methods were necessary. The Board of Agriculture offered to supply vaccine free of charge to inoculate cows in infected herds in Oxfordshire, the Local Education Authority employing veterinary surgeons to do the inoculation and undertaking to keep complete records of each animal inoculated. Many farmers were willing to try the treatment. In most herds two or three cows abort each year, and from inquiries made it would seem that there are very few herds in the county which have not suffered or are not suffering from contagious or epizootic abortion.

Fourteen infected herds were selected for the experiments and were chosen from the following groups; (1) Herds where above 20 per cent. of the cows aborted in the year previous to the beginning of the experiments, and where the disease had been prevalent for several years; (2) Herds where less than 20 per cent. of the cows aborted in 1910, but in which several of the cows regularly aborted each year; (3) Breeding herds, where practically no outside animals are brought into the herd; (4) Herds where very little rearing is done and in which cows are being continually brought in from outside.

There are no data available to calculate the loss due to this disease annually to the county. It would probably be greatly exaggerated if it were assumed that the percentages of abortion throughout the county due to this disease were equal to the results obtaining with the controls (*i.e.*, the uninoculated animals) in these herds, but if for the purposes of this report this assumption is made then the loss in the county would reach at least £30,000 per annum, even when the at present low value of 35s. per calf is taken and when the depreciation in market value of a cow which has aborted is taken at £5.

It is the opinion of several prominent Oxfordshire dairy farmers that the loss due to each case of abortion may be estimated at between £7 and £8.

In these experiments as 18 out of every 100 uninoculated animals (controls) aborted, the assumed number of cases of abortion per annum would be 18 per cent. of 23,824—the total number of cows and incalf heifers in county—*i.e.*, 4,288 cases of abortion. Taking the loss for each case at £7, the total loss would be about £30,000 per annum. No value has been assigned to the breeding value of the cow to the owner and to his loss when he is compelled to buy cows in order to keep the yield of milk up to his contract.

Even if not more than 10 per cent. of the herds are affected, and there is reason to suppose that this is a low estimate, the loss to the county must reach several thousands pounds per annum, and therefore anything that can be done to reduce this loss must be of great value to the dairy farmers.

Two methods of immunisation were tried:—

IMMUNISATION OF NON-PREGNANT COWS OR HEIFERS

"**Anti-Abortion A** is injected into non-pregnant heifers or cows two months before they are put to the bull in the hope that they will resist infection when exposed in a herd in which contagious abortion exists and carry their calves to full term. The anti-abortion is injected under the skin of the neck. Heifers are usually immunised, but any empty cows or heifers which have aborted or not, should be immunised. Twenty-five per cent. of the empty cows or heifers on such farms should not be immunised but left as controls, for it is by comparison of the after behaviour of the immunised and the unimmunised (*i.e.*, controls) that the value of the method is to be judged. If both methods—Anti-abortion A and B—are being tried on the same farm, 25 per cent. of the cows and heifers will act as a control to both methods.

IMMUNISATION OF PREGNANT ANIMALS.

Anti-Abortion B. Small doses are injected under the skin of the neck of pregnant animals monthly, the first injection to begin immediately they have ceased bulling after service, and the last during the seventh month of pregnancy. No first injection should be given later than the first month of pregnancy. Twenty-five per cent. of the cows and heifers on the farm should be left unimmunised as controls. If both methods are being tried on the same farm 25 per cent. of the total cows and heifers will act as a control to both methods.*

Table showing the number of animals under treatment and how they calved :—

	Anti- Abortion A.	Anti- Abortion B.	Controls.
Animals	253	112	296
Heifers	70	0	51
Cows	193	112	245
Aborted	15	17	54
Barren	22	12	13*
Calved correctly	223	83	229

* At first 167 controls were left, and of these 13 were barren, but later the number of controls was further increased to 296—all uninoculated animals in a herd being taken as controls—and the total number of controls that were barren is not known.

The term "heifer" is here applied to all females up to the time of having their first calf, after which they are called cows.

The following is a summary of the results :—

Before experiments began (during 1910) 28·9 per cent. (i.e., about 1 in every 4 animals) aborted.

After Anti-Abortion A treatment, 5·7 per cent. (i.e., about 1 in every 18 animals) aborted.

After Anti-Abortion B treatment, 15·1 per cent. (i.e., about 1 in every 7 animals) aborted.

Among the controls 18·2 per cent. (i.e., about 1 in every 6 animals) aborted.

When it is considered that there was a tendency to inoculate all the animals it was thought most likely to abort, and that the animals under Anti-Abortion A treatment were on the average younger than those left as controls and therefore more likely to abort, the results are on the whole much in favour of the Anti-Abortion A treatment. In most of the herds it was the exception for a cow which had once aborted to be kept and bred from again. Altogether 66 cows which aborted in 1910 were inoculated.

THE TREATMENT OF ABORTED COWS.

	Animals.	Aborted.	Barren.	Calved Correctly
Anti-Abortion A	43	2	12	29
" " B	13	6	2	5
Controls	10	4	4	2

The results on cows which aborted in 1910 were :—

Under Anti-Abortion A treatment, 4·6 per cent., or 1 in every 21, aborted again.

Under Anti-Abortion B treatment, 46 per cent., or 1 in every 3, aborted again.

Left as controls 40 per cent., or 1 in every 3 aborted again.

A great deal of trouble had been experienced on some of the farms before the trials began owing to the number of heifers aborting. On those farms where the trouble was the greatest most of the heifers were inoculated and very few left as controls.

"A" TREATMENT ON HEIFERS.

	No.	Aborted.	Barren.
Anti-Abortion A	70	4	5
Left as controls	51	7	4

5·7 per cent., or 1 in every 17 of the heifers under Anti-Abortion A treatment, aborted.

13·7 per cent., or 1 in every 7 of the heifers left as controls, aborted.

In some general notes on the Oxfordshire experiments, Mr. Bland says no separation of the affected and suspected animals was attempted during the trials. The inoculation did not upset the animals to any great extent. On some farms the cows undergoing the B treatment gave slightly less milk at the night's milking on the day of the inoculation. Slight swellings were noticed in some cases after inoculation. The swellings disappeared in about three months. The A treatment has on the whole given better results than the B treatment. On those farms where the heifers had been aborting for some years, there were very few cases after inoculation with Anti-Abortion A, and on two or three farms where this trouble was the worst, not a single heifer aborted after inoculation. Of cows which had aborted before inoculation only 1 in every 21 aborted after the A treatment. It will be noticed from the foregoing results that there has been a sudden decrease in the number of cases of abortion among the inoculated animals on practically all the farms. If this had been an isolated instead of an average result, and had been true of the controls also, then it might have been put down to the disease wearing itself out on a particular farm, but this could hardly be the case at all 14 centres, for as mentioned before, the centres were chosen from farms falling into four very dissimilar groups. The animals under the Anti-Abortion A treatment have consistently calved better than those left as controls, even although the controls in most cases were chosen from older animals.—*Farmer and Stockbreeder.*

REPORT OF THE VETERINARY DEPARTMENT OF THE GOVERNMENT OF THE GOLD COAST FOR THE YEAR 1912. [ABSTRACT]

The staff sanctioned for the year was one veterinary officer, one veterinary dispenser, one dispenser pupil, and one 6th grade clerk, being no increase over the staff granted for the year 1911.

The dispenser pupil, Mr. Anyawuo, resigned and left on the 19th April. There was considerable difficulty experienced in filling this vacancy. Suitable youths who have passed Standard VI. or VII. would not come forward to undertake to learn this class of work at a salary of £24 per annum. The vacancy was, however, filled by an Ashanti youth named R. W. Kaye who has passed Standard IV.; he commenced his training on October 2nd. From the 19th of April to the 17th of September the available staff to carry on the technical work at headquarters was the veterinary dispenser.

Finance.—The approved estimates for the year were as follows: Colony £242, Ashanti £486, Northern Territories £486. Total, £1,214.

The approximate expenditure was about £714. The revenue collected during the year was £273 11s., which was paid into the local Treasury. Taking the approximate expenditure as £714, and the revenue collected as £274, it shows that the department cost the Government for the year about £440.

The work of the department has increased two-fold over that of previous years. The amount of correspondence and clerical work which has to be attended to by myself at times prevents me doing as much scientific work as I could wish.

The work carried out during the year has been (a) Teaching and training dispenser pupils; (b) Teaching farriery; (c) Daily inspection of horses belonging to Government officials; (d) Promoting better stable management; (e) Clinical work; (f) Veterinary inspec-

tion, Coomassie Town; (g) A study of the local cattle trade; (h) The daily inspection of imported cattle and the collection of Kraal fees; (i) The collection of statistics of the importation of live stock into Coomassie; (j) The inspection of animals for exportation from Coomassie; (k) The promotion of the hide, skin, and bone trade; (l) Inspection of horses and mules at Accra; (m) Inspection of cattle at Accra; (n) The study of contagious and infectious diseases together with an investigation of an outbreak of trypanosomiasis amongst horses and mules at Accra; (o) The study and collection of helminths affecting live-stock and poultry; (p) Blood work, examination of blood smears, blood counts, differential leucocyte counts, and haemoglobin tests.

HORSES AND STABLES, COOMASSIE.

In my annual report for the year 1909 I remarked on stable management, which I thought very necessary. The outcome of those remarks, which were adopted, has led gradually to a better management of horses and stables and in consequence the animals are in better health and condition. The period of life has been lengthened.

There are no Government stables in Coomassie. The existing 34 brick stables have been built privately by the officers of the Gold Coast Regiment.

No. 1 Stable 10 loose boxes built in January, 1910.

No. 2 " 16 " " in Jan. and Dec., 1912.

No. 3 " 8 " " in July, 1911.

The type of loose box is very satisfactory. The walls are of burnt brick, the ground area is 10ft. x 12ft., open in front with a 7ft. verandah; corrugated iron roofing; brick and cement manger and bucket stand on the floor. The floor is made of broken brick which is dug up and removed every six or eight weeks.

More loose boxes are badly needed, as the surplus horses have to be stabled in swish and grass stables, which are difficult to keep clean and rainproof. Outside, there are standings for every horse where grooming takes place.

Every stable is provided with a circular sand-bath 15 yards in diameter and surrounded by post-rails 7ft. high. The sand is river sand and not salty. Horses are put in these sand-baths every morning and night. The effect on their coats is excellent, and it also helps a horse to "dry off" more quickly after exercise.

All bedding is spread out in the sun all day to dry. Excellent straw is now being obtained from the trading firms, who have been good enough to allow officers to take away all that is available.

Food. Excellent dhoo grass is obtainable in sufficient quantity. It is not allowed to be cut before 10 a.m. in the dry season, or before 1 p.m. in the wet season. Immediately on being brought to the stables it is spread out to dry and not given to the horses till night time. No grazing is permitted before 4.30 p.m. at any time of the year, and then only if there has been sufficient sun.

Maize is the staple grain used here and on the coast. Comparing the analyses of maize with that of oats, which experience has proved is the best grain to feed horses on, maize is wanting in mineral salts, and also possesses a low nitrogenous ratio; for these reasons bran has been recommended to be added to the maize and is now being imported, and can be landed at Coomassie at 16s. 6d. per 112lbs. A good mixture on which the horses do well on here is half maize and half bran—7½ lbs. to 10 lbs. of each according to the size of the horse.

Guinea corn is the staple grain north of the Volta. It is good feeding, the horses like it and I think highly of it. It can, however, only be purchased in small quantities at an excessive price in Coomassie. The analysis of this grain is not available at present.

Enquiries were made with a view to getting oats out, but the price proved prohibitive. A ton of best English oats landed at Secondee would cost £16 13s. 4d. to which must be added 10 per cent. customs duty and railway freight (£5) Secondee to Coomassie. If the Customs duty and railway freight were lowered for this commodity horseowners here would be prepared to import English oats. In the treatment of trypanosomiasis the condition of a horse is the main factor, and a food substance has to be given that can easily be assimilated, for in this disease a horse quickly wastes. I am of opinion that English oats would be a success, and I strongly urge the reduction of Customs duty and railway freight enabling it to be imported here.

The system of dividing the daily feed of corn into "two feeds" as is done at Accra is against all experience. Three is the fewest number of feeds the day's corn should be divided into, but four or five feeds are better, if it can be carried out satisfactorily.

Dung pits have been condemned and are abolished. Horseboys now carry all excreta and soiled bedding, etc., to the incinerators, where it is immediately burnt. This system has very markedly lowered the number of biting flies about (chiefly stomoxys).

It should be remembered that the horse is not a forest bred animal, but comes from the plains of the north, where the climate is totally different to that here. Coomassie is a town situated in a clearing in the Ashanti forest. To keep horses fit and well in a country like this, no deviation from the common rules of stable management should be allowed.

Farriery.—At the commencement of the year, the shoeing work was handed over to the Pioneer Company Gold Coast Regiment, but still has the supervision of the veterinary officer. The wear and tear of the unshod foot in this iron-stone country is tremendous. It is said that the average growth of the hoof of the horse is about four inches a year. The experience arrived at here on close observation is that the majority of horses in hard work require shoeing at the end of each month, the shoe being worn out at the toe; this means practically the wearing away of three inches of iron in comparison to the growth and wear of four inches of horn.

There are four farriers in Coomassie who were trained by this department. Their work improves with experience, so much so that when time expired they will be able to take their place at any of the towns where shoeing of horses and mules in transport work is adopted.

In the month of November two constables of the Northern Territories Constabulary arrived to undergo a course of training in this art. I am quite pleased with the progress they have made.

Clinical Work, Coomassie. At the close of the year there were 52 horses in the Military lines, 12 in the Hausa Zongo, and one in the town. There were also 3 mules in Millers Transport Department.

During the year two horses were anaesthetised with chloroform for surgical operations, one horse taking 4 ounces for the removal of a scirrhus cord, and the other taking 8 ounces for the operation of castration.

The number of cases treated was 151; of deaths was 15, five of which occurred in the Hausa Zongo; and of horses destroyed, 2.

The four diseases deserving some mention and remarks are paralysis (lumbar), pneumonia, trypanosomiasis, and verminous cachexia.

Paralysis (lumbar region) was very common in Coomassie before the advent of the Veterinary Department, and was feared more than any of the other diseases affecting horses. There are several diseases which cause paralysis of the hindquarters, but what is the precise cause of this disease here I cannot state as I have not seen a case. The characteristic symptom is stated to be a paralysis of the loins, which comes on suddenly,

and death occurs in a few days. The mortality here is said to be 100 per cent. There were three of these cases treated during the year, two of which were shot, and the other case was sufficiently cured to walk away and be sold; it, however, had a relapse and died two months afterwards.

Pneumonia. It appears that during the third quarter of the year there was an epidemic of pneumonia. The veterinary dispenser reported that five horses in one month died from this disease, three in the military horse lines and two in the Hauza Zongo.

CATTLE TRADE—COOMASSIE.

The trade in cattle from the French Territory north of the Northern Territories shows an increase over the trade done last year. There has been a slight decrease in the trade from the Ivory Coast. The trade in cattle indigenous to the Northern Territories is still very small; a reference to Table III. shows that there were 491 not humped cattle imported during the year. These cattle came part from the Northern Territories and about half of them came from the Ivory Coast and Banda District of Ashanti.

Several Moors from the Sus country have been noticed to be importing cattle from the French Timbuctoo district. Buying has been keen throughout the year, several buyers have come from Eastern and Western Akim, and also from the Saltpond district.

The price of live cattle fluctuated from £3 10s. to £9 10s. depending on the season, and the number of cattle in the market. A record price of £9 10s. for a bullock was paid by a Greek butcher during the year.

Importation of Live Stock, Coomassie. The statistics kept show 63 horses imported during the year, but the number is believed to be something nearer 80.

In August, Millers Limited, Coomassie, imported four mules from the Canary Islands for their transport department. One of these was shot in September, the remaining three are still working. A Hausa mule was brought down from the Hausa country, and returned there with a load—it was a fine animal.

For the last three years it has not been usual for the kola traders to bring their donkeys as far as Coomassie; however, during this year several donkeys have come in.

There was one camel imported which lived for about five weeks. I regret to say he died at Mampon, having been ridden from Coomassie to Mampon a distance of 32 miles in one day.

The number of cattle imported for the year was 10,942 being an increase of 2,291 over the year 1911. During the year there has been a great improvement noticed in the condition of cattle on arrival here. In dealing with diseased cattle, *i.e.*, cattle suffering from extreme emaciation and in the advanced stages of disease, our old plan was to refuse admission; now we quarantine them. There were 21 cattle thus treated during the year and all died during the 24 hours period of detention. The greatest diplomacy is exercised when seizing these animals.

Table III. shows the number of cattle imported compared with the year 1911. They have been classed as humped and not humped. In the humped, or Zebu, two types have been noticed.

Type I.—known as Moshie cattle, is well known to the natives as a fast walker. The description of this type may be expressed as follows:—a leggy animal, with a long back, with poor sloping quarters; in consequence the tail is situated about a foot below the horizontal dorsal and lumbar vertebrae. The head is long and lean.

Type II.—comes from a district which is said to be about a month from the Moshie district. The headquarters of this type is said to be at Douentza. This type is a stumpy animal with a short back, wide quarters, and the tail is situated a few inches below the horizontal dorsal and lumbar vertebrae. The head is

short and broad. These arrive at Coomassie in better condition than the Moshie cattle. They are said to be very slow walkers.

The predominant shape of the horns in both types is the shape of the lyre. The colours are mixed with white predominating. It is rare to see a pure red, or a pure black, or a pure white; pure roans are fairly common. The comparative weights of the two types are not given as there is no weighing machine in Coomassie that can accommodate the weighing of live cattle.

There are no statistics kept by this department of the number of sheep and goats imported into Coomassie; the staff at present at its disposal cannot spare the time to do so, as these animals come in at all hours of the day, and also by several different roads. The number is believed to be decreasing that is, if any reliance can be placed on the statements of the butchers who complain of the scarcity of sheep and goats for killing, and also that the Ashantis are buying these animals on the route down. The Ashantis are keen buyers, and their transactions are for ready money; this gives them a preference over the Mahomedan butchers, who buy and kill before paying. It appears that these purchases are more for breeding purposes than for killing as they are driven out of Coomassie.

There were 6 male ostriches imported during the year. One of these died here, and three were exported by road to Obuassie. The remainder are kept in a compound about 14 feet square, and are fed on the tops of the sweet potato, and dusa, a native bran. These importations are to supply an itinerant trade in feathers. Coomassie is not a suitable place for the rearing or keeping of ostriches, but ostrich rearing might be carried on profitably in the Northern Territories, especially in the Volta region. The price of an ostrich is about £3.

Exportation of Cattle, etc., from Coomassie. There was a great decrease in the number of cattle exported by railway to stations down the line. This decrease is attributed to the closing down of several mines and to the great reduction of staff at others.

Since the date when the rules governing this exportation came into force, on the 1st August (published in *Gazette* No. 22/1912) we have passed 1,137 head of cattle for exportation by railway and have rejected three head. The total number of cattle inspected for exportation was 1,510.

During the five months that these regulations have been in force we have passed 373 head of cattle for road exportation.

The trade in cattle by road exportation has greatly increased. It is to be regretted that all cattle exported in this way are not inspected, but we have not a large enough staff to carry out or strictly enforce the above regulations; however, we do insist on all cattle which are intended for the mines being presented to us before 10 a.m.

Several complaints were made to this office during the year concerning the irregular arrival of cattle trucks. It is a pity the railway department do not keep the cattle trucks at this end of the line. Cattle dealers and butchers cannot afford to keep cattle hung up here where there is a scarcity of good grazing.

The total number of sheep and goats passed for exportation by railway was 275.

Slaughter-house, Coomassie. The slaughter-house is under the control of the Medical Department. The veterinary dispenser paid 60 visits for the collection of specimens; the helminths found were the usual ones.

Hide, Skin, and Trade. The trade in hides from Coomassie during the year shows a great increase over the export of last year. There has been a boom in the English hide market which has naturally affected countries exporting hides. Owing to this activity in England the local price of sun dried hides advanced from 5½d. per lb. to 9d. per lb.

Last year the trade was practically in the hands of the Mahommedan community, but this year several of the cocoa and rubber brokers have also taken up this class of trade.

Three complaints were made to this department by merchant firms of the "doping" of hides. As these hides are bought by weight the sellers have turned their attention as to how they could increase the weight, and have done so by hanging them up and pouring water over them until they were saturated and then placing them in the mid-day sun to dry. This only renders the hide surface dry, and complete evaporation has not taken place and in consequence the hide is heavier than one dried in the ordinary way by slow process where complete evaporation has taken place. When a hide of this kind comes into the hands of the merchant it is stored away, waiting for shipment, and not being properly dried putrefactive changes take place in the hide. In the tanning process these blemishes come out and can be noticed.

The number of hides exported from Coomassie for the year was 20,370, as against 8,500 for the year 1911. Taking the average sun dried hide as weighing 12 lb., and at its present price, *i.e.*, 9d. per lb., this represents a local trade of £9,166.

Sheep and Goat Skins. According to the returns sent into this department there is a commencing trade in sheep and goat skins. These might be used in the manufacture of chrome leather and its imitations. The number exported from Coomassie during the year was 988.

Bone Trade. No available information is at hand whether any bones have been exported during the year. But during the last quarter one consignment of several sacks of horns was exported. The result of this experiment is as yet not known.

[Notes on inspection of stud of horses and mules at Accra used in transport work, and of cattle in the Accra district, are given].

CONTAGIOUS AND INFECTIOUS DISEASES.

Anthrax. During the year there were three sporadic cases of anthrax at Coomassie.

Contagious Bovine Pleuro-Pneumonia. No epidemic of this disease as occurring in the Colony was reported to this department during the year. But we saw twenty-five lungs affected with pleuro-pneumonia in the Coomassie slaughter-house in the imported cattle. From information gathered from cattle traders it appears that this disease is gradually dying out in the French Moshie district, but is spreading to the cattle of the Coryanza district north of the Moshie territory.

Filariasis. Two cases of filarial infection were diagnosed in horses. One case at Coomassie and the other at Accra. Both specimens when stained appeared to be of the same species.

Piroplasmosis. Three blood smears prepared by the veterinary dispenser from cattle under suspicion and quarantined in our isolation pound show classical *P. bigeminum*.

Infectious Pneumo-Enteritis of Sheep or Pasteurellosis Ovis. During the month of August there was a serious epidemic of this disease among sheep and goats in the village of Christiansborg. On the 8th September I visited this village and found one dead sheep and four dead goats and post-mortemed one sheep and one goat. I examined all the sheep and goats in the village and detected four sick, two of which were killed, and the remaining two were isolated for the purpose of observation, one of which died the same night and the other on the 10th September.

Four post-mortems were made and the lesions observed were the same in all. There was pneumonia and enteritis, the heart showed petechiæ, and there were

numerous petechiæ on the peritoneum covering the bowel and abdominal cavity, the mesenteric glands were swollen and hæmorrhagic, the livers showed fatty degeneration. The spleen was normal in size but the pulp was soft and easily broken.

Bacteriological Examination. Blood smears were prepared from the peripheral veins, heart, lungs, liver and spleen, and smears were made from the scraping of the mucous membrane of the bowel. The smears were stained with methylene blue, fuchsin, and giemsa. The organism found was a bacillus of the fowl cholera type which is always found in these so-called hæmorrhagic septicæmias. The smears prepared from two of the animals which were found dead were contaminated with the bacillus of malignant œdema.

The number of deaths reported during this epidemic was forty-four. One owner losing the whole of his flock of twenty-five sheep and goats.

Tetanus. One case of tetanus was observed in Accra in a newly imported Spanish mule; it was a case of infection of acne sores, by allowing this mule to roll on the ground.

Trypanosomiasis at Accra. During the year there was an epidemic of this disease among horses and mules at Accra. The history of the epidemic was furnished me by Dr. O'Brien, Medical Officer of Health, and is as follows:—During the month of May two mules belonging to the Accra Town Council were sick. Trypanosomiasis was not suspected until a report was received that there was a sick horse at the Victoria Hotel. Dr. O'Brien examined the blood of this horse, which showed a heavy infection of trypanosomes. Following on this he examined the blood of all the Town Council's mules and found four mules infected with trypanosomes. The above is the history of the true epidemic. But at the end of the month of May eleven horses were brought into Accra by the retinue of the late Governor. These horses were bought in the Northern Territories and had travelled through Ashanti along the banks of the River Volta, where they became infected. Ten of these horses died or were shot during the month of June.

Between July 30th and September 9th, I examined the blood of 83 horses and mules at Accra, the results were furnished in an Appendix to Quarterly Progress No. 10, and showed that I had found four horses and one mule infected.

The problem to be solved is, what was the source of infection for the four mules and one horse that Dr. O'Brien found infected, and the three horses and one mule I found infected (the mule was one of the mules of the Town Council).

A reference to the records of blood examination of cattle killed at the Accra slaughterhouse shows trypanosome infection existing among cattle there from the commencement of the year 1911. These cattle are derived from a herd kept by Hausamen and are replenished by breeding locally, and from the Addah district, with an occasional importation from the Northern Territories, French Soudan, and Togoland. Therefore this herd must be viewed as a reservoir for spreading trypanosomiasis.

The question now comes, how was the disease spread to the horses and mules concerned in the true epidemic. Authorities have found and all agree that the tsetse fly (*i.e.* Glossina) when infected can convey the disease to healthy animals through their bites. Before the advent of the railway, Accra was considered free from tsetse flies for a radius of four miles, but during the year tsetse flies have been caught within the neighbourhood of the railway station and the laboratory. During the six weeks I was working there I only saw one tsetse fly, which was caught, and identified by Dr. Donnal as a specimen of *G. morsitans*; however, these flies cannot be said to be common in the locality, in fact might be

2

3

considered a rarity. On searching for other blood sucking flies which are viewed as suspicious in the mechanical transmission of trypanosomiasis, I came across two species of *Stomoxys* and one species of *Lyperosia*, these flies were very common, especially among the cattle, and they will always maintain an endemic form of trypanosomiasis among the local herd.

The evidence collected by myself re three of the horses infected, is interesting. Two of the horses belong to Hausa cattle owners; these Hausamen take no care of their horses and frequently ride them among the cattle, and it is most probable that they were bitten, and always will be bitten by infected flies which have flown off after a meal off infected cattle. The horse that Dr. O'Brien found infected at the Victoria Hotel originally belonged to a Hausaman, who gave it to the owner of the Victoria Hotel, this horse was in a dying condition when the exchange of ownership took place. The distance between the Victoria Hotel, where this horse was stabled, to the stables of the Town Council is about 30 yards, no great distance for infected stomoxys to fly, and it is most probable that this is what did occur, and that this horse was the reservoir for infecting the Town Council's four mules. The fourth horse is a horse belonging to a European, and was stabled behind his bungalow, around which stable I saw cattle grazing frequently, and here again it is most probable that this horse was bitten by infected stomoxys.

The species of trypanosome concerned in the true epidemic showed a marked morphological resemblance to *T. cazalbouli*.

Experimental Work. On the 20th of August I inoculated four healthy animals with virulent blood from Kotey's bay pony No. 1. This pony is the sole survivor of the batch of 11 horses imported into Accra by the retinue of the late Governor. The result of my experiments were as follows:—

- (a) Goat, grey female, well nourished, in kid about 11 months old. Injected intraperitoneal 2.5 c.c. blood. Trypanosomes first seen on 29th August. The goat aborted on 7th September, examination of the foetus proved negative. The goat died on 2nd October, she lived 43 days after the date of inoculation.
- (b) Dog, white male, well nourished, about six months old. Injected intraperitoneal 2 c.c. blood. Trypanosomes first seen on 2nd September. The dog died on 27th September, he lived 35 days after the date of inoculation.
- (c) Guinea-pig, black, well nourished. Injected intraperitoneal 1 c.c. blood. Trypanosomes first seen on 2nd September, and died on the 7th. This guinea-pig lived 17 days after the date of inoculation.
- (d) Guinea-pig, white, well nourished. Injected subcutaneous 1.5 c.c. blood. Trypanosomes first seen on the 7th September and died on the 9th. This guinea-pig lived 19 days after the date of inoculation.

Morphology. The morphological characters of the majority of the trypanosomes seen in the smears prepared from this horse was a small trypanosome, its posterior end being in the shape of a pike head, a vacuole situated close to the centrosoma, a feebly developed undulating membrane without a free flagellum, the nucleus was placed centrally and was oval in shape. In the blood smears prepared from the experimental animals (a) and (b) the undulating membrane was well developed showing on an average $1\frac{1}{2}$ folds, and without a free flagellum. The majority of the trypanosomes from (a) i.e. the goat showed vacuoles, whereas in the dog and the two guinea-pigs no vacuoles were seen. The posterior end varied in shape.

The conclusion to be derived from these experiments is that the species of trypanosome infecting this horse is either *T. congolense* or *T. pecorum*.

TRYPANOSOMIASIS, COOMASSIE.

At Coomassie in treating these cases in horses we have had considerable success. Reference to the clinical statistics shows that twenty-eight horses were treated for this disease, out of which eight died. Of these deaths four occurred among the horses of the Hausa Zongo. The treatment laid down for the year was the combination method of treatment of atoxyl and orpiment. The procedure adopted was an injection subcutaneously of atoxyl 60-75 grains, depending on the size of the horse, on two consecutive days, followed by an interval of one day with no treatment, and then by the administration of orpiment 60 grains, given in a drench for three consecutive days.

This treatment is carried on for a month, but during the latter days of treatment the horse must be carefully watched for toxic symptoms of arsenic. To avoid this it has been our practice during the third and fourth weeks to carry out the treatment on a full stomach—the horse is fed with corn one hour before treatment. During this period the temperature must be taken morning and evening and registered on a chart, as the temperature chart is the guide for further treatment. After the first week of this treatment it is useless to examine the blood for trypanosomes as they are generally not to be found in the blood taken from the peripheral circulation. Our experience in acute cases is that, when a horse is handed over to us for treatment the temperature may be anything from 103°F.—106°F. During the first month's treatment the temperature gradually comes down to about 100°F. in the morning, and 101°F. in the evening. In chronic cases the temperature is generally about 102°F., and at the end of the month's treatment the morning temperature is about 99°F. and the evening temperature about 101°F. Our second month's treatment generally consists in dropping the orpiment, and in its place treating any symptoms that appear, as example, if the horse is anæmic he is given iron and strychnine, if he has worms he is treated for worms, if he is inclined to be "liverish" he is treated for liver trouble.

The third month's treatment consists in the treatment of a convalescent patient by tenios and gentle exercise; if at the end of this month the temperature has been normal for about twenty-one days, the case may be discharged and put into hard work.

A liberal diet of corn must be given and it should be spread over into five feeds daily; should a horse absolutely refuse to eat its corn it must be fed with any of the following: eggs and milk, stout, Ghari (i.e. native flour and water), boiled sugar cane, boiled artichokes, boiled beans. As previously mentioned, diet and condition are some of the principal factors in the treatment of this disease. Unless a horse is in good condition it will not be able to stand the arsenical treatment.

Prophylactic Measures. As was shown in last year's report, the administration of some arsenical preparations in a tsetse fly district was of some use as a preventative against this disease. During the year we recommended a cheaper form of arsenical preparation than osudan, namely arsenic alb (white arsenic). Grains, 2-3 to be given daily when trekking through fly country.

HELMINTHIASIS.

During the last three years we have treated numerous cases of worms in horses. In the cases where worms have been found in the dung and have been treated successfully, these patients have been returned in our "Clinical Statistics" as cases of entozoa, whereas on the other hand when treated not successfully they have been returned as cases of verminous cachexia.

Verminous Cachexia. This disease comes on towards the end of the rainy season, and is liable to be

mistaken for trypanosomiasis. But frequent blood examination of the patients' blood reveals no trypanosomes. The blood does show a picture of anæmia due to the infestation of the stomach and intestines with both blood sucking and non-blood sucking helminths which are always seen in the subsequent post-mortem of these cases.

In our dispensary at Coomassie we have a good assortment of worm medicines, including arsenic, antimony, mercury, creosote, male-fern, thymol, turpentine, aloes, and linseed oil, none of which seem to be beneficial in these cases.

The post-mortem is remarkable for the fact that although the horse has been treated with worm medicines for about three weeks, and has passed hundreds

of worms in the interim, yet countless numbers of worms are discovered in the post-mortem.

This disease, in my opinion, is caused by feeding horses on grass that has not been properly sun-dried, which is frequently the case during the rainy season. The remedy which suggests itself is to make hay, thus rendering the ovas of the different species of worms inactive. Several specimens of different species of worms were collected during the year and were presented to the Helminthological Laboratory of the London School of Tropical Medicine.

W. P. B. BEAL, Veterinary Officer.

VICTORIA VETERINARY BENEVOLENT FUND.

The Annual General Meeting was held at 10 Red Lion Square, London, W.C., on Wednesday, June 3rd. At a well attended meeting there were present:—Sir John M'Fadyean, Sir Stewart Stockman, Messrs. H. A. MacCormack, S. H. Slocock, F. W. Garnett, S. Villar, G. A. Banham, W. J. Mulvey, J. Ward, A. Spicer, T. S. Price, J. Abson, Capt. Rees-Mogg, Professor N. Almond, G. Thatcher, William Shipley, and others.

In the unavoidable absence of the President (R. C. Trigger) Sir John M'Fadyean was unanimously requested to take the chair.

The minutes of the previous meeting were read and confirmed.

The annual report, which had been printed and circulated [see p. 789, our issue of June 6] was received and adopted.

Messrs. A. Spicer, H. Sumner, Sir Stewart Stockman, R. C. Trigger, S. Villar, and S. Wharam, who had been nominated for Council of the Fund, were declared elected.

It was proposed by Mr. Villar, seconded by Mr. Banham, and carried unanimously, that Mr. P. J. Howard be elected to the other vacancy on the Council, to fulfil the expressed wish of a further Irish representative.

It was proposed by Mr. Banham, seconded by Mr. Slocock, that the Auditors—Messrs. Woodger and Lark, be re-elected; this was duly carried.

It was unanimously adopted, on the proposition of Sir John M'Fadyean, that a hearty vote of thanks be

given to the auditors for the great trouble and care they had taken with the accounts.

On the proposition of Mr. Gooch, seconded by Prof. N. Almond, and supported by the Chairman and other members, a hearty vote of thanks was recorded to the Hon. Sec. and Treasurer.

Alleged Negligence—Verdict for the Veterinary Surgeon.

At Hull County Court on Friday, June 5th, before Judge Fossett Lock and a special jury, Thomas Hill, mineral water manufacturer, of Hull, sued Frank Bradley, of 20, Charlotte Street, Hull, veterinary surgeon, for £99 6s. 6d., as damages for alleged negligence as his veterinary surgeon in respect of a bay hunting mare purchased by plaintiff on December 10th, 1913.

Mr. J. H. Payne appeared for the plaintiff, and Mr. Harry Wray represented the defendant.

The plaintiff alleged that the defendant on December 10th last, after an examination of the mare, negligently advised the plaintiff that the animal was sound, and was not suffering from corns, in consequence of which plaintiff purchased the animal for £130, whereas the animal had splints on both forelegs, corns on both forefeet, and spavins on both hocks, and was unsound. The particulars of claim set forth the price paid for the mare by plaintiff, £130; nine weeks' keep of the mare, £9; less net amount realised by sale of the mare by public auction, £39 13s. 6d.; leaving as the amount of the claim £99 6s. 6d.

The evidence for the defence was continued, and several witnesses were called to the effect that the mare was not constitutionally lame.

Frank Topham, blacksmith, of Coniston, deposed that he had shod the mare and never saw any indications of corns.

Albert Roe, who for 14 years had been groom to Mr. Richardson, farmer, of Wyton, said that he remembered the horse being foaled. The horse was not constitutionally lame.

George Robert Simpson, a member of the Royal College of Veterinary Surgeons, practising in George Street, Great Driffield, deposed that on Tuesday, January 13th last, he visited the premises of the plaintiff, together with Mr. Bradley, for the purpose of making an inspection. The inspection was fixed for the 16th, and witness attended on that day with Mr. Bradley. Mr. Sowerby was also present. Witness was told that the horse was alleged to be wrong in the wind and had got spavins and splints. The mare was saddled and taken to a field and galloped for about a mile, but witness found no evidence that she was wrong in the wind. The mare did not grunt. In the opinion of witness, there were no spavins. The mare had good hocks. There were no curves. There was a little splint on each leg. The mare was not lame. On April 8th he saw the mare again, and some corns had been cut out previously, and had, in his opinion, been cut out about a week.

Lieut.-Col. Longhurst, F.R.C.V.S., veterinary surgeon, gave evidence that he examined the mare and found a slight corn under the heel on each foot. The animal was a little lame. There were small splints on the fore-legs. A vein on the near hock was a little larger than the corresponding one, but there was not any unsoundness. The hocks of the animal were sound.

The jury found for the defendant with costs. They found that there was no negligence on the part of the defendant in certifying that the horse was sound on December 10th last. The jury did not find from the evidence that there was any unsoundness in the horse on December 10th.—*The Hull Times*.

A Tuberculous Cow—Conviction for Failure to Notify.

The first prosecution in Surrey under the Tuberculosis Order of 1913 took place on Saturday, at the Kingston-on-Thames County Police Court, when Owen Older, a dairy farmer, of West Molesey, was summoned for having in his care a cow suffering from tuberculosis with emaciation, and failing to give information to the police or to an inspector of the local authority, as required by the Tuberculosis Order of 1913. He pleaded "not guilty."

Mr. C. G. Sherwood appeared for the defence.

P.S. Parish said that on Tuesday, May 12, he went to a meadow known as America, adjoining Field Common, Walton, and saw an aged red cow, the property of the defendant, in a very emaciated condition, coughing frequently but feebly, and suffering very much from diarrhoea. Witness reported the facts, and the same afternoon saw Mr. Owen Older and told him that he was dealing with it as a suspected case of tuberculosis. Defendant said, "I have had two veterinaries to see it, and they said it was suffering from John's disease." On May 25 witness served a summons on him for failing to notify the case, and he said, "Very well, thank you, I thought it was John's disease."

Cross-examined, witness said the defendant might have said that he was carrying out the treatment recommended by the veterinary surgeons.

Mr. W. Caudwell, F.R.C.V.S., an inspector of the Surrey County Council for the Chertsey and Hersham Police Divisions, said he received a telephone message

from the last witness, and accompanied him to the meadow, where he found an aged shorthorn cow in milk and in a very emaciated condition. Witness made a full examination of the cow, and found crepitation in both lungs and disease of the udder. Witness formed the opinion that it was suffering from an advanced condition of tuberculosis, and its condition was such as to have suggested to anyone familiar with cattle the existence of tuberculosis. Witness at once sent notice of slaughter, and afterwards made a post-mortem examination at which the defendant had the opportunity of being represented, but did not avail himself of it. Witness found that the animal had suffered from miliary tuberculosis of both lungs, and of long standing. There was also tuberculosis of the glands and intestines, and disease of the udder which was not of a tuberculous character. He had received no notice of the case from the defendant.

Cross-examined by Mr. Sherwood, witness said that in his opinion any veterinary surgeon who examined the cow must have known that it was suffering from tuberculosis, and it was his duty equally with the defendants to have reported the case.

Mr. Sherwood, for the defence, said his clients were dairy farmers in a large way of business and owning a great number of cows. At the end of January this cow was seized with illness, and Mr. Older called in his veterinary surgeon, who prescribed for it, and said it was suffering from John's disease. Defendant could not do more than carry out the advice of the veterinary, and he isolated the cow in a meadow where there was a good feed of grass, and gave it also hard food. Defendant would have had the cow destroyed at once if he had suspected that it was suffering from tuberculosis, but he had not the slightest idea that it was suffering from that disease.

Defendant Owen Older was sworn, and gave evidence bearing out his solicitor's statement.

In answer to Superintendent Marshall, defendant admitted that from the end of January to May 12th no veterinary surgeon had seen the animal.

Mr. J. W. Whitecross, veterinary surgeon, said he examined the defendant's herd on the previous day, and thought it was one of the finest in Surrey.

Mr. T. S. Payne, veterinary surgeon, of Hersham, said he was called in by the defendant on January 4th to see the cow, which was suffering from diarrhoea, and he prescribed for it. Since January 9th he had not seen or heard anything of the animal. He only examined it casually, and saw no evidences of tuberculosis. There had been ample time since for the development of tuberculosis.

The Bench decided to convict, and the defendant was fined £5 and £1 14s. 6d. costs.

Cruelty Charge Dismissed—Costs Allowed

Mrs. Anne Cheesman, fruiterer, 42 East Street, Epsom was summoned for working a horse in an unfit state.

Inspector White, R.S.P.C.A., stated that as the horse appeared lame in the near fore leg he stopped defendant, who was driving it, and she said that the animal knocked one of its knees a few days previously. Witness examined the horse and found that the lameness was slight and of a temporary nature. Underneath the saddle, however, was a large wound, apparently an abscess, and when witness touched it the horse went down on its knees in acute pain. When he asked defendant why she was working the horse in such a condition she said, "It's had a bad back, but we thought we would cure it."

Alexander Piesse, veterinary surgeon, stated that when he went to put his hand on the horse's back it cringed,

but he was told that this was its habit. There was a swelling on the back.

Defendant stated that the horse was very nervous as the result of a fire, and always flinched whenever anyone touched it. It knew her, and she could harness it without any trouble.

Mr. Talbot, veterinary surgeon, corroborated defendant's story as to the animal's nervous condition, and stated that it was so nervous that a stranger probably would not be able to harness it.

The Magistrates viewed the horse, and on returning the Chairman remarked that everyone was liable to make mistakes. In this case there was nothing the matter with the horse as far as they could see, and they dismissed the case.

Defendant asked for costs. She had had to hire a horse and bring the veterinary surgeon there that day.

The Magistrates allowed costs, £1 13s which the Society would have to pay.—*Mitcham Advertiser*.

Sale of a Shorthorn—Tuberculin Test.

In the King's Bench Division, on Wednesday, May 27, before Mr. Justice Rowlatt, Mr. James Charles Lewis, Duncote Hall, Towcester, Whittlebury, Northamptonshire, sued Lord Burnham for 115 guineas, the price of a shorthorn cow, which was sold by plaintiff to Mr. Richard Spencer Britten, as agent for Lord Burnham, on Oct 24 last.

Defendant refused payment on the ground that the cow had failed to pass the tuberculin test. Plaintiff, on the other hand, maintained that the condition of sale that the cow should pass the tuberculin test was subject to that test being made before the animal was taken away from Whittlebury.

Mr. Spencer Bower, K.C., and Mr. Grimwood Mears (instructed by Mr. Bertram Sturt) were for the plaintiff, and Mr. Pollock, K.C., and Mr. G. M. Hilbery (instructed by Messrs. Henry Hilbery and Son) represented the defendant.

Opening plaintiff's case, Mr. Bower said that the cow in question, "Duchess of Bartlow IX," in the catalogue which appeared as "Lot 21"—(Laughter)—was sold by auction by Mr. Webb, of Messrs. John Thornton and Co. on Friday, Oct. 24. and on Monday, Oct. 27, the animal was delivered to defendant. About Dec. 12 defendant purported to reject the cow, which plaintiff refused to take back. Defendant set up that there was a condition that where a purchase was effected at over 80 guineas the animal should pass the tuberculin test. This meant, according to defendant, that he would have the right, without giving notice to plaintiff, to have at his own place at any time and by any person, any tuberculin test, and if the cow failed to pass the test he could reject the animal. Plaintiff admitted that there was a condition that anybody who purchased any of the animals on the day of the sale should have the option of a tuberculin test, provided he made arrangements for that purpose and got the test applied at the farm before the animal was removed. If that was the condition, defendant had not complied with it, because Mr. Britten gave an unconditional order for delivery on the Monday, pursuant to which the cow had been delivered. A month after the sale defendant made up his mind to reject, having had that horrible mass of tuberculosis—

Mr. Justice Rowlatt: Don't harrow us. (Laughter.)

Mr. Bower added that there was a counter-claim for the keep of the cow. He wanted to know what had been done with the milk.

Mr. Pollock replied that the milk had been run down the drain. The Burnham herd was rather a good one, and tuberculous milk would not be knowingly sold.

Mr. Justice Rowlatt: Might not you give it to the pigs?

Mr. Pollock: Then you would produce tuberculous pigs. (Laughter.)

Mr. Justice Rowlatt: I can't understand how any man or any animal is alive at this period of the world's history. (Laughter.)

Plaintiff said that as no test was made at his farm he assumed that Mr. Britten did not wish to have a test made.

Cross-examined by Mr. Pollock, plaintiff said that a good deal was heard from some people about tuberculosis in cattle, but he did not attach much importance to it. If the test had been made at his farm, and the cow had reacted, the sale would have been off.

Mr. Webb, senior partner of Messrs. John Thornton and Co., stated that he had written to Mr. Britten, offering to have the test made at Whittlebury, but he had no authority from plaintiff to do so.

Among other witnesses were three who made purchases, and who said that they heard the auctioneer mention that purchasers could have the tuberculin test, but that it must be made at plaintiff's farm.

Mr. William Bateman, one of these witnesses, expressed the opinion that in the North of England 70 per cent. of the dairy cattle would fail to pass the test, but he did not think that mattered very much. If they had to run down the drains all milk which failed to pass the test they would get on very poorly.

Mr. Justice Rowlatt: You will want a new and expensive drainage system. (Laughter.)

DEFENCE.

Mr. Pollock submitted that plaintiff had failed to make out a case. Here was a definite agreement made with plaintiff as to stock about eighty guineas before the sale began, and Mr. Britten would tell his lordship that no term was imposed that the test should be at Whittlebury as part of the condition, or that there was in any way any limitation. It was perfectly reasonable that the test should be at Whittlebury, and no doubt that was the place at which it ought to take place. Still, the test was to be a condition of the sale.

It was quite clear that defendant should have the test, and that, although it was reasonable that the test should take place at the farm, it was, by mistake, not held there, and when the cow reacted in the test there was no sale. Therefore defendant was not bound to take the cow at the price of 115 guineas or at all.

His Lordship remarked that that was not a great price for a cow.

Mr. Pollock said he had known a bull calf go to 700 guineas.

Mr. Bower suggested that it might be possible to cure a cow of tuberculosis.

His Lordship asked whether the cow should be sent to a health resort in the Alps for a cure. (Laughter.)

Mr. Pollock said that to imagine Lord Burnham was endeavouring to get out of the bargain merely for £10 was quite out of the question.

Mr. Justice Rowlatt: As a matter of fact, I think it is irrelevant.

Mr. Britten gave evidence in support of Mr. Pollock's statements. His conversation with Mr. Lewis took place before the luncheon in the cowhouse.

Mr. Justice Rowlatt: The conversation, not the luncheon, was in the cowhouse? (Laughter.)

Mr. Britten added that plaintiff said he would give the test for animals for which over 80gs. was paid. Witness did not take particular note of what the auctioneer said about the tests, because he (witness) had already made the arrangements with plaintiff. He was very particular about the test. After the cow arrived on the Monday afternoon he wrote a letter in which he said he presumed the animal had been tested, for otherwise she would not have arrived by that time. After the test had been made at Hall Barn by Mr.

Walker, veterinary surgeon, he did not think it would be a good thing to use the milk. The cow was not put with the herd, but was isolated.

Cross-examined by Mr. Bower, witness said he did not hear plaintiff say that the test was to be made at the farm, but he was not prepared to deny that plaintiff said that.

Mr. F. P. Matthews, a partner in the firm of Messrs. John Thornton and Co., who was present when Mr. Britten and plaintiff met, stated that he heard plaintiff say he would give a test for any animal bought for 80gs., but he did not hear words "at Whittlebury."

Mr. Manuel, veterinary surgeon, of Wolverhampton, said that on the instructions of the auctioneers he went to examine the cow, in addition to others, at Whittlebury, on the Monday, but the animal had been sent away before he went there. He was of opinion that the tuberculin test was a right test, and was very important.

Mr. Bower: Whether you can get tuberculosis through drinking milk is another question. You say it is conclusive in all cases?

Witness: It is not exactly invariable, but it is perfectly reliable.

Mr. Justice Rowlatt: The condition here was not for that fact, but for the test.

After hearing speeches by counsel, his lordship said he would give judgment next morning.

JUDGMENT.

Mr. Justice Rowlatt said he came quite clearly to the conclusion that the bargain was that there should be a tuberculin test if any animal was knocked down to Mr. Britten at over £80. Prima facie, his lordship could not see any ground for supposing that the test should be anywhere but at Whittlebury, and from the correspondence that prima facie view was corroborated. As soon as the question arose plaintiff and Mr. Webb (the auctioneer) took that position, and it was really never contested by Mr. Britten in the correspondence. Mr. Britten gave a delivery order which simply said: "Deliver this cow by rail on Monday," the sale having taken place on Friday. That did not bind him until it was acted upon. It certainly could not be said that the terms of the delivery order could be cut down by the terms of the sale note so as to make it read: "Deliver on Monday, provided there has been a test." Therefore it came into the hands of plaintiff's bailiff as a perfectly open delivery order, and the bailiff was bound to act upon it unless it was countermanded.

His lordship did not think that it was premature to send the cow on at nine o'clock in the morning, and he was sure the bailiff acted in perfectly good faith. The legal effect was that Mr. Britten did not waive his right to a test, but simply did not exercise his option, and therefore the contract became absolute. It was also said that it was plaintiff's fault that the cow was not tested before being sent off on the Monday. It seemed to his lordship that the testing was a matter entirely in defendant's hands, and that plaintiff had no initiative in the matter.

Clearly the auctioneer had no higher degree of authority than his principal to meddle with the matter and it was clear that he acted simply in a good-natured way to facilitate business when he wrote to Mr. Britten suggesting that the cow might be tested on the Monday by the veterinary surgeon who was to test other animals. Unfortunately the letter got to Mr. Britten late on Saturday night, and he took no steps.

The real truth was that Mr. Britten did not realise that the veterinary surgeon would not have got there on the Saturday—whether he ought to have realised it or not did not matter—and therefore that the terms of the delivery order would bring the cow before she had been tested. That was the unfortunate thing that had

happened. The trouble was due really to Mr. Britten himself, because he had given the delivery order and had not thought out the situation and taken steps to make sure that there was to be a test before the delivery order took effect. It was his affair to see to that, and unfortunately he jumbled it. In these circumstances plaintiff must recover.

Judgment was entered for plaintiff for 115gs. on the claim and on the counter-claim (for keep, etc., of the cow), with costs.—*Daily Telegraph*.

PARLIAMENTARY.

MILK AND DAIRIES BILL.

In the House of Commons on Tuesday, June 9.

Mr. HERBERT SAMUEL (Yorks, Cleveland) formally moved that this Bill be now read a second time, [See our issue May 16th, p. 750, and May 23rd, pp. 753, 767].

Mr. C. BATHURST (Wilts., Wilton,) supported the second reading. He said agriculturists did not welcome restrictive legislation, but they realised that it was inevitable in the face of public opinion. They desired, however, that producers should not be penalised in respect to offences after the milk had left their possession. He believed the dangers of dirty milk were minimised as much as those of tuberculous milk were exaggerated. During the summer months a large proportion of infantile mortality was due to the effect of dirty milk, but with regard to tuberculous milk he held that it had yet to be proved that bovine and human tuberculosis were identical or interchangeable. He recognised that the right hon. gentleman had endeavoured to treat the producer with as much fairness as was possible in the circumstances, and that the Bill compared favourably with all of its four predecessors. Apparently it was provided that medical or other officers of urban authorities, who were the authorities for the areas of consumption, were not to attempt to invade the areas of production. He hoped that in Committee amendments making this quite plain would be accepted. There was, he understood, to be no interference with the structure of cowsheds, and for this he thanked the Government, for nothing was more likely to reduce the production of milk or to increase its cost than interference with the premises in which cattle were housed. He suggested that the presence of the veterinary surgeon employed by the owner of the cattle should be permitted when animals were inspected by officers of the local authority. This would be only fair to the producer. He thought that the expenses of administering the Bill ought to be borne by the Exchequer, the service being in the nature of a national service as human health was involved, but he urged that in any case it should be made clear that half of the entire expense would be defrayed out of the Exchequer and that not more than half would fall on the local authorities. The Central Chamber of Agriculture, the British Dairy Farmers' Association, the Central Land Association, and other agricultural organisations were unanimous in asking the House to accept the second reading of the Bill and in hoping that it would not be drastically amended in Committee.

Dr. ADDISON (Hoxton), said that the Bill would introduce for the first time something like unanimity in administration. It would be administered by the officers of the larger authorities, who would be in the main well trained and experienced and would avoid placing harassing and futile restrictions on the milk producers. He associated himself with the suggestion that, in some form or other, there should be a system of certification of the quality of milk. The indirect effect of such a system would be vastly more important in improving the general quality of the milk supply than

the Bill itself, because, if the milk were graded as it was in New York, people would begin to inquire why grade A was different from grades B and C, and there would be created a public opinion in favour of clean milk.

Mr. FORSTER said that they would, he thought, make a great mistake if they were to divide against the second reading. This Bill would do something to check the sale of impure milk, but it would not make it cheaper or more plentiful, and he was not at all sure that it would not rather encourage the importation of foreign milk than the development of the home supply. With the development of preservatives, it was quite possible that the importation of foreign milk might grow to an extent that none of them would desire. He regretted that the Bill did not do something to assist the farmer to obtain immunity from disease in his cattle.

Mr. ASTOR (Plymouth): The first clause was entitled "The prohibition of the sale of tuberculous milk." It was difficult to make a calculation as to the amount of tuberculous milk in London, but it was something like 10 per cent. They could not afford to wipe out 10 per cent. of the milk supply of the country. He would like to see the clause amended so that there would be a regulation of the sale of contaminated, tuberculous, and dirty milk, and a gradual lifting up of the whole supply. Clause 1 had another danger. It said that a seller should not knowingly sell tuberculous milk. That opened an awful possibility of litigation.

It seemed to him the first step they wanted to make was to classify milk according to its quality, and then gradually to try to improve the quality of uncertified milk. The great advantages of certification, or grading, were that it established a standard of purity; the public knew what it bought. It was impossible suddenly to produce pure milk without diminishing the supply, but classification and certification would make it possible gradually to improve the supply without diminishing its quantity or raising the price. Grading had been tried on a voluntary basis in a large number of areas in this country. In his own constituency the local sanitary officer circulated periodically among the big consumers of milk a list of the dairy farmers and milk producers who submitted themselves to a special inspection, and the system worked satisfactorily without raising the price of milk.

He regretted that the President of the Local Government Board had not provided in the Bill for the licensing of milk sellers. The old system of registration of milk sellers was condemned without qualification by the Irish Milk Commission in their final report of 1911. The Commission pointed out that the local authorities had no power to refuse registration on the ground that the applicant's premises were unsuitable, and that procedure by prosecution in the case of offences was cumbersome, uncertain, and possibly ineffective. Only the other day the Carnarvon County Council prosecuted some milk sellers for selling dirty milk, and the fines of 10s. each imposed by the magistrate were set aside at quarter sessions on the ground that the offence was a technical one. The county council were thus put to the expense of £60 without result.

Mr. BARNSTON (Cheshire, Eddisbury): The right hon. gentleman had produced a Bill dealing with admittedly a very difficult and delicate subject on fair and sound lines, and if those lines were adhered to, he promised him a good deal of support from the Opposition side of the House.

Mr. STANIER (Shropshire, Newport) pressed for an assurance that the Bill would be strong enough to deal with the contamination of the London milk supply while the cans were being handled *en route*.

Mr. HILLS (Durham) appealed to the Government to codify all the existing Acts dealing with milk.

After further debate,

Mr. HERBERT SAMUEL thanked the House warmly for the reception given to the Bill. The methods in the Second Schedule for arriving at the really guilty person by tracing the milk back had been criticised, but those methods were now in force in Manchester and were a great success.

He agreed that it was essential so far as they could to maintain the cheapness of the milk supply, and this Bill would be a mischievous Bill if it had the effect of sending up the price and rendering less of it available to the poorer classes. He did not believe it would do so. The regulations they had in mind would not involve cost but care. Care and cleanliness need not be costly. He had not in mind expensive alterations to cowsheds all over the country—(cheers)—and other ideal measures. It had been urged that the county authorities should be given powers instead of the district authorities. It must, however, be borne in mind that there was already legislation dealing with this matter and under the Diseases of Animals Act it was the district councils which appointed the veterinary officers and inspected cattle. With regard to the expenses of local authorities, if the whole cost of paying the salaries of officers was thrown on the Exchequer they must necessarily become officers of a central Government Department. In the Finance Bill of this year it was proposed that half the salaries of public health officers should be paid out of public funds, and it was intended that that term should include veterinary officers. He recognised the force of the contention that it was desirable to codify the older Acts, but one had to consider Parliamentary exigencies. If, however, there was any general desire, he would be very glad after the passage of this Bill to introduce a new Bill of a codifying character without making any change of legislation, but bringing all legislation on the subject into one statute.

He was much disappointed by the speech of the hon. member for Plymouth. With his interest in public health he thought the hon. member would be more likely to complain that the Bill was too much watered down than that it was too stringent. He agreed with the hon. member that they must improve gradually. He would remind the hon. member that Clause 3 and the First Schedule were in substance the model milk clauses which now existed in a hundred local Acts of Parliament. The hundred boroughs which had obtained powers under those Acts would certainly not be prepared to give them up without some substitute for them. It would be impossible to carry through the House of Commons any Bill which swept away all these local statutory powers and substituted no similar law of a general character in their stead.

Nor was the proposal for licensing milk sellers likely to find favour in the House. Desirable as it would be in many ways, it would give rise to much Parliamentary opposition. He had little doubt that the milk traders—and they were powerful—would soon make their voice heard if any attempt were made to establish a licence system for the sale of milk, as there was for the sale of alcoholic liquor.

He did not, however, view with any spirit of hostility the hon. member's proposal for establishing a system of graded and certified milk and protecting the producers of certified milk from the competition of others who might seek wrongly to use the term "certified milk." All he said was that that was not a substitute for the proper regulation of the whole milk supply, though it might be a useful supplement. He was quite content to leave that to discussion in Committee, and if it appeared that the proposal to have regulations made for protecting those who chose to sell certified milk—not making it obligatory, of course—and for penalising those who wrongly claimed the title "certified milk" com-

mended itself to the Committee he would be quite ready to be guided by the opinion of the Committee.

Sir F. BANBURY criticised Clause 2, which, he said, would enable the President of the Local Government Board to make regulations which need not lie 40 days on the table of the House by calling them "Special Orders." He also asked what Clause 9, which allowed sanitary authorities to establish and maintain depôts for sale of milk for infants, had to do with the provision of pure milk. That was a matter of municipal trading. As nothing was said about price, local authorities might be induced to sell milk considerably under cost price. In that case, what was to become of the trader?

The Bill was read a second time.

MILK AND DAIRIES (SCOTLAND) BILL.

On the motion for the second reading of this Bill, Captain GILMOUR (Renfrewshire, E.) on behalf of Scottish agriculturists, welcomed the Bill, but intimated that there were various points upon which amendments would be suggested.

Mr. MCKINNON WOOD (Glasgow, St. Rollox) stated that the Bill was the result of conferences with the Chambers of Agriculture in Scotland and others interested in agriculture, and was to a large extent an agreed Bill. At the same time he promised to give to Committee points sympathetic and open-minded consideration.

The Bill was then read a second time.—*The Times*.

THANKS TO ELECTORS.

*To the Fellows and Members of the
Royal College of Veterinary Surgeons.*

Gentlemen,

I beg to tender my most sincere thanks to those gentlemen who supported me at the recent election of Councilmen of the Royal College of Veterinary Surgeons.

I shall welcome any suggestions which have for their object the advancement of our profession from any of the Fellows and Members and they may rely upon my giving them full consideration with a view of bringing the same before the Council.—I have the honour to be, gentlemen, your obedient servant,

J. CHARLES COLEMAN.

Swindon, Wilts. June 6.

Dear Sir,

Allow me, through your columns, to thank those gentlemen who have so generously accorded me their support at my four elections to the Council. I am particularly grateful because I have never sought the support of any Society, but have trusted solely to the individual members of my profession to vote for an absolutely independent and unbiassed candidate to that august body.—I am, gentlemen, your obedient servant,

GEO. A. BANHAM.

Dear Sir,

Please permit me through your columns to return my very sincere thanks to all those who so kindly voted for me at the recent Council election. I only hope I may prove worthy of their confidence.—Yours faithfully,

P. J. HOWARD.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, June 5.

REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. E. Brown to be Major. Dated June 2.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

W. G. Thompson to be Lieut. Dated May 18.

His Majesty the King held a Levée at St. James Palace, on Wednesday, June 10. The following Noblemen and Gentlemen attended:—

* * *

Vet.-Major W. A. Pallin.

Lieut. J. Scott Bowden, Welsh Division T.F., has passed for promotion to Captain in subjects B 2, 3, 16 Territorial Force Regulations.

OBITUARY

Dr. J. R. Green.

We regret to announce the death of Dr. Joseph Reynolds Green, Fellow and Lecturer of Downing College, who passed away on Wednesday, June 3rd, in his 66th year. His sister, with whom he had lived for many years, died about a fortnight ago.

Dr. Joseph Reynolds Green was the son of Mr. Daniel Green, of Bedford, and a brother of Mr. George Green. He was born in 1848 at Stowmarket, Suffolk. After a private education, he entered Trinity College in 1881, and graduated in the First Class National Science Tripos, Part II. (in Botany and Physiology) in 1884. He took his M.A. in 1888, and his Sc.D. in 1894, and was elected a Scholar of his College. He held the post of Senior Demonstrator of Physiology in the University from 1885 to 1887. In 1890 he was the Rolleston Prizeman (Oxford). Dr. Green was elected Fellow of Downing College in 1902, and in the same year he became President of the Botany Section of the British Association. From 1887 to 1907 he was the Professor of Botany for the Pharmaceutical Society of Great Britain. He also held the post of Hartley Lecturer in Vegetable Physiology in the University of Liverpool. He was a Fellow of the Royal Society. Dr. Green was the author of several books on botany and vegetable physiology.

Dr. Green always took a keen interest in religious and social work in Cambridge, and was for many years a deacon of Emmanuel Congregational Church. Though he never took an active part in politics, he was a consistent Liberal. He was a well-known Mason, and had held many offices.

Many prominent residents and members of the University attended the funeral service at Emmanuel Congregational Church, on Saturday afternoon.

The interment afterwards took place in Trumpington Churchyard.—*Cambridge Daily News*.

[Dr. J. R. Green, M.A., F.L.S., D.Sc., acted as an examiner for the Diploma of Membership R.C.V.S., 1893—1906. He will be remembered by many who were then students].

Mr. P. F. F. TAYLOR, V.S., Urmston, Manchester, died on May 21st from acute pneumonia. Aged 62 years.

CORRESPONDENCE.

COLONIAL APPOINTMENTS.

Sir,

The very pertinent letter signed "East of Suez," which appeared in your issue of the 28th of February last was read with great interest by many members of the profession in the various Colonial services.

The inadequacy of the supply of suitable candidates for civil veterinary appointments at home, in the Colonies and India is no doubt partly due to the reduction in the numbers of young men now entering the various Colleges and completing the course as compared with fifteen or twenty years ago, but the dearth of candidates for some Colonial appointments is largely due to the position occupied by the veterinary service which "East of Suez" rightly describes as "an off-shoot of another Department." In this connection I enclose the minutes of a meeting of veterinary surgeons held in Bulawayo in April last. A copy of the same was forwarded for the consideration of the Council of the Royal College of Veterinary Surgeons, and the Secretary replied that the matter had received the attention of the Parliamentary Committee and he was instructed to state that "as the Departmental Committee on the Public Veterinary Services had already completed their report, the Committee felt that they could not profitably take any action on the resolution." I am not aware of the composition of the Committee referred to (the Public Veterinary Services Committee), nor have I seen the terms of reference on the subject, but it seems somewhat strange that in regard to the Colonial Veterinary Services more extended enquiries were not made amongst members who have spent

the whole of their professional lives in the Colonies. No doubt the Committee did make some such enquiry, but as far as I know not a single member of the profession in Southern or Central Africa was consulted or afforded an opportunity of expressing his views.

As there will probably be a large number of Colonial veterinary surgeons at home for the International Veterinary Congress, I venture to suggest that a conference be held, and the matter of Colonial appointments, conditions of service, etc., be considered.—Yours truly,

J. M. SINCLAIR, M.R.C.V.S.

Salisbury, S. Rhodesia. May 18.

Sir,

I see an advertisement in May 9th issue, where the Colonial Office is hard put to it for professional men. It may be of use to our professional brethren to insert the following.

The East African Protectorate vacancies are partially caused by death. Mombasa is not Brighton. None of the appointments are plums.

Young members, or members who contemplate applying should consult the Colonial Office list for information of Colony.

The ultimate aim of every official is for pension. The nicer the bait (salary) the nastier the hook (appointment). Pensions are computed on the number of years service, and 1-60th of salary per year's service is the rule in most colonies. After ten years a man may claim 10-60th of his salary as his pension, but the Government may hold you for thirty years from time of admission. Resignation loses all pension. Q.E.D.—Yours truly,

ONE IN IT.

JUNE 20, 1914

VOL. XXVI.

BOARD OF AGRICULTURE—ANNUAL REPORT OF THE CHIEF VETERINARY OFFICER FOR THE YEAR 1913.

Sir Stewart Stockman's annual report is now to hand, and contains much valuable information. This week we deal only with that portion which relates to scheduled disease, leaving other important matters for consideration in a future note.

The report commences with foot-and-mouth disease. The two outbreaks which occurred in 1913 are fully described, and the points of epizootiological interest noted. In neither case could the origin of infection be traced, though in one—the Sussex outbreak—there was a possibility of virus having been carried over by seabirds from the north of France.

Some other diseases are dealt with very briefly. Equine mange is decreasing; but, as the Order against it has only been in force a comparatively short time, the chief officer has little to say upon it. Tuberculosis, which was only scheduled in 1913, is touched very lightly in the report for a similar reason. The Tuberculosis Order was in force for the last eight months of the year, in which time 4,720 cases reported under it were confirmed. The Chief Officer remarks that the returns are "of considerable interest"; but the late arrival of many of them has obliged him to postpone their analysis for a future report. Next year, probably, we may expect some detailed consideration of the results of the Tuberculosis Order—in the meantime, the figures show how sorely the Order was needed.

Anthrax has decreased once more; but we still think that there must be much unreported disease. Only 23 cases in horses, for instance, are reported this year—surely too small a figure. The Chief Officer makes some important observations regarding anthrax. He reminds us that an exhaustive enquiry a few years ago proved "that infection in about 80 per cent, of the cases was due to virus imported from counties where the disease is enzootic." He concludes that "This being the case, it must not be expected that the decline in the number of outbreaks will be continuous, as the incidence depends largely on occurrences outside this country." Clearly, then, the Anthrax Order

can do little more than what the Chief Officer tells us it was designed to do, viz.—"Control the spread of anthrax once a case has occurred on premises, and prevent a recurrence of the disease."

Certainly it is succeeding in this so far as reported disease is concerned; but how much exists unreported?

On the whole it seems probable that anthrax will still be with us when every other disease now scheduled has disappeared.

Sheep scab also has decreased, but not so markedly as in previous years. This is due partly to importation of infective sheep from Ireland, but much more to another fact which makes that importation unavoidable, and also increases our difficulties with indigenous disease. It is now known that acari may live months and even years upon a sheep without causing noticeable symptoms of disease—and this, by the way, suggests a line of enquiry in the question of recurrent equine mange. Our present Sheep Scab Order will eradicate the disease in time—but the time will be longer than was once expected.

Swine fever has decreased a little, but this may be only one of its numerous and inexplicable fluctuations. The position is admitted to be unsatisfactory, so a new experiment is to be made. It will be remembered that the Departmental Committee on Swine Fever advised that the Board should undertake field observations upon selected premises with regard to serum treatment. This is to be done, and the Chief Officer details the procedures he proposes to adopt. Of course the consent of owners will be necessary, but that is not likely to be difficult to obtain.

The section upon glanders is very interesting. The disease decreased in 1913, but only very slightly indeed. The Chief Officer analyses the returns, and brings out several points. The Mines Act accounted for six outbreaks in imported Russian ponies. Further, its influence led one colliery company to test its entire stud in different stables, thus causing nine outbreaks to be recorded as separate ones. Finally, one hitherto undiscovered centre of infection accounted for sixteen outbreaks more. The Chief Officer concludes "the apparent absence of success, then, of the operations against glanders in the past year is not real." We add that the history of glanders for this year, so far, wholly supports his view. Again, the proportion of recurring outbreaks was very high in 1913; and this, indicating as it does more frequent re-testing, is another hopeful sign. The report suggests the possibility of blood tests being adopted in the near future. But we think that mallein alone will suffice to eradicate glanders.

DEATH OF A FOAL—TOXICITY OF MORPHIA?

Subject. A male Clydesdale foal, born normally and without assistance during the night of May 29th, a few days prior to full time. The following morning, May 30th, the foal appeared weak and could not rise or remain standing without help, and persistently refused to suck till about 10.30 that night, when having gained considerably in strength during the day, it commenced for the first time to take nourishment naturally. During the day frequent attempts had been made to induce the foal to suck, but finding them unsuccessful the mare was milked into a cup and the milk administered to the foal—evidently much against its will—both by spoon and by rubber teat on the end of a bottle. During this period loose respiratory rales in the neighbourhood of the larynx and trachea became audible.

The following morning the foal had improved to a remarkable degree; it was sucking frequently and freely, and except for occasional tracheal rales, appeared as healthy, bright, and lively as could possibly be wished for till about 2 p.m., when indications of abdominal pain were noticed. The abdomen was drawn up, the abdominal muscles tense, and the patient evidently uneasy and distressed. The bowels and urine had been in every way normal up to now.

These unfavourable symptoms became rapidly worse, and by 4 p.m. it was quite apparent that the foal was suffering acute abdominal pain. The rectum, as far as could be explored, was empty. About 2oz. of castor oil with 30 minims Collis Brown's chlorodyne were administered, a few ounces of cow's milk, raw eggs, and whisky having been previously given by the attendant. Hot fomentations were applied to the abdomen, and about 8oz. of soapy water rectally injected. In half-an-hour's time the evidence of abdominal pain had become still more intensified and the patient appeared to be suffering extreme agony. There was some difficulty in drenching him or persuading him to swallow, and I therefore decided—wisely or unwisely—to administer half a grain morphine sulph. hypodermically. A little later the pain appeared to be considerably relieved, the patient went quietly to sleep, and died seemingly in his sleep about 8 p.m.

Autopsy the following morning revealed nothing abnormal on opening the peritoneal cavity. On slitting up the alimentary track several feet of the small intestine showed marked venous congestion of the mucous membrane. Stomach, caecum, and large intestine normal. One small mass, about the size of a filbert, of dense, impacted, faecal matter was present in the small colon. Remainder of abdominal contents normal. Heart and lungs healthy. A large quantity of whitish froth was present in the trachea, extending from the larynx down to many of the larger bronchi, but not extending to the bronchioles or lung tissue. No

other abnormality could be discovered in any other organ or tissue of the body. There was red clot in both sides of the heart.

Queries and Observations. 1. To what extent was this foal "killed by kindness," coupled with morphia?

2. Should a weakly foal that refused to suck be forcibly fed during the first 24 hours? If not, at what age should, or may, forcible feeding be resorted to if still declining to suck?

3. Is refusal to suck, when newly born, at all a common condition in foals or calves? (I am credibly informed that the human infant is frequently given no nourishment of any kind during the first three days of life).

4. Is the drenching or forcible administration of milk a particularly risky or undesirable procedure in the newly-born foal, on account of the danger of fluid entering the trachea? In this case there seems no doubt that the froth in the trachea simply represented milk that had "gone the wrong way," and the appearance of the trachea distinctly suggested that if the foal had survived longer, mechanical pneumonia might have supervened, unless the froth therein became in some other way disposed of. (There was no indication, post-mortem, of pulmonary oedema or congestion).

5. The mare had been in full lactation for a week or more prior to foaling, the milk flowing freely from the udder. The first (colostrum-containing) secretion was thus no doubt wasted through leakage. Might this account for the intestinal congestion, or was the latter more likely to have been set up by the small impacted mass in the floating colon? (There appeared to be no damming back of the bowel contents anterior to this mass).

6. Are there any grounds for the opinion apparently popular amongst the "laity," that a mixture of cow's milk and raw eggs is of value as a laxative for foals?

7. Finally, to what extent was the half-grain of morphia responsible for death? I have a strong suspicion, on reviewing the case, that it probably had a considerable share. Appearances certainly pointed to it, and had not the foal (fortunately) been my own property, I think I should have lost my client as well as the patient! I know that morphia is regarded with the greatest awe by medical men for the *young* of the human species, but have never heard that the same applies to the equine infant. I am of opinion that it is almost impossible to kill an adult horse with morphia.

Any remarks or comments on the above case by practitioners experienced with foals would be much appreciated by the undersigned.

C. H. H. JOLLIFFE, F.R.C.V.S.

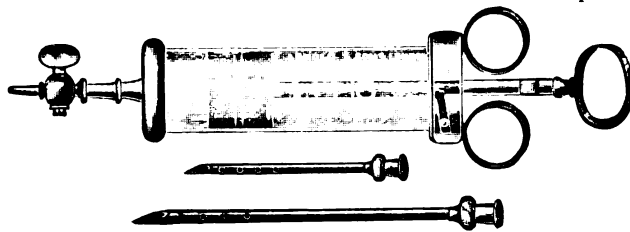

Pickering, Ontario, Canada.

GOVERNMENT PUBLICATIONS.—Messrs. Wyman and Sons, Ltd., official sale agents in England and Wales for Parliamentary papers and Stationery Office publications have issued the following:—Board of Agriculture for Scotland, second report, 1913, price 10d.

A DESCRIPTION OF TWO NEW INSTRUMENTS AND THEIR APPLICATION IN PRACTICE.

Lung Puncture Syringe for extracting germ-laden material through the chest wall in pulmonary diseases.

To procure morbid material laden with tubercle bacilli or other bacteria from a given centre in the living animal body harbouring these bacteria, is not always an easy procedure, nevertheless to those clinicians who are called upon to make their diagnosis by the isolation of the causative organism it is essential. In those cases of pulmonary tuberculosis, as seen in our non-expectorating patients, the difficulties of obtaining sputum are many, and when obtained in the usual manner per os or nasum, during the process of exit and later on transit, the materies morbi is liable to become contaminated by alien bacteria, and in the case of tuberculosis by acid-fast bacilli morphologically resembling tubercle, thereby increasing the danger of errors in diagnosis. To obviate these risks and difficulties I have suggested penetrating the chest wall in selected cases, plunging the needle attached to a suitable syringe into the lung parenchyma and aspirating what liquid or semi-liquid there is to be found.

The syringe has a capacity of 50 cubic c.c. The barrel is made of very strong graduated glass into which is placed a perfectly fitting metal plunger. The needles are two in number, with wide bore and bayonet points, measuring three and four inches long respectively. To permit of lateral suction there are several small perforations made along the wall of the needles at their distal ends. When fluid has been aspirated a stop-cock which is fixed between the approximate end of the needle and the barrel of the syringe can be utilised, serving a double function, as follows: (a) Before the removal of the needle from the chest the stop-cock is turned off, in this manner preventing the materies morbi collected by the syringe from becoming contaminated by alien atmospheric bacteria, a most essential detail where bacterial cultures are desired. (b) The stop-cock brought into play makes the syringe serve as a carrier of morbid material, doing away with the necessity of carrying a sterile receptacle for the purpose. A careful examination of the chest wall of the suspected animal should be made, i.e. auscultation (stethoscopic)—auscultation direct should be relegated to the past—and percussion, with the view of ascertaining the exact physical state of the lungs and locating the most disorganised area or areas. The hair should be clipped and the skin painted with strong tincture of iodine, allowed to dry, and repainted at two intervals. The animal should now be held, nosed and horned, by an attendant, and the anterior border of the rib noted. The needle of the sterile syringe is plunged boldly into the lung structure, care being taken to avoid the intercostal vessels which run along the posterior border of

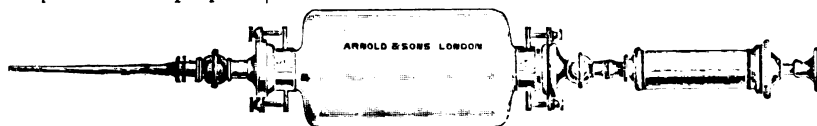

each rib. Where the examination makes us reasonably suspect an infective pulmonary abscess cavity, steady withdrawal of the plunger will fill the syringe with purulent material. Where no such collection of morbid liquid exists, as for example in miliary tuberculosis or pneumonia, it is imperative before plunging the needle into the chest to take up 5 to 10 c.c. of sterile water, sterile normal saline solution, or sterile broth, the latter being particularly necessary where we desire eventually to make cultures from the aspirated material. The syringe now charged with the selected fluid the needle is driven home, after which I gently move it to and fro to break down the lung structure in a small area and make, so to speak, a kind of pultaceous cavity. The fluid is then injected, allowed to remain 30 to 60 seconds and aspirated. The resultant collection will depend for its composition upon the pathological state of the lung itself. It may be purulent, thick or thin, it may be a sanguineous or a sero-sanguineous fluid. If sterile precautions are carefully adhered to no possible danger can follow the operation.

Up to the time of writing I have made over one hundred lung punctures in horses, cattle, and the dog without a single bad sequel, and in the same animal I have punctured the same lung in several places at the same time without the least apparent inconvenience to the patient. Where the puncture is made with the object of identifying the tubercle bacillus it must be pointed out that negative results may not mean the absence of tuberculous lesions, for example, lung puncture in cases of glandular lesions only would possess no diagnostic value. Where pulmonary morbid material is required for the cultivation of the causative bacteria with the view of making vaccines, the advantages of lung puncture over the collection of sputum obtained in the usual way are obvious. In the former where sterile precautions are taken, the risk of alien bacterial contamination is done away with altogether.

Milk Aspirator for the collection of germ-laden milk, particularly Tuberculous Milk, from the udder of a cow.

It is an acknowledged fact that sometimes cows harbour tubercle bacilli in the milk gland and apparently give milk which is tubercle-free, at least centrifugalising and careful microscopical examination of the resultant deposit of such milk often gives negative results. It is just possible in those cases the bacilli may be adherent to the mucosa, or, in any case, infective foci may be found projecting from the mucous membrane which under a certain degree of suction may be compelled to break down and give up the bacteria. Reasoning thus I have devised a milk aspirator.

This instrument is composed of a cylinder made of stout glass with a capacity of 300 c.c., at one end of

which is an aspirating pump, and at the other a tapering needle for insertion in the udder. At each end of the cylinder a stop cock is inserted so that all the air can be expelled, the stops applied, and a vacuum remain for a considerable length of time. The distal end of the needle has several lateral perforations, while the approximate end is gradually widened to the base so that the teat sphincter may closely fit the needle, preventing the ingress of outside air.

The cow should be held by an attendant and the hind legs "spanned," failing this the tail should be drawn in between the hind legs, brought round the hock at the same side as the operator, and held by an attendant. This tends to prevent the instrument or the operator being kicked. The end of the teat should now be scrubbed with cotton-wool soaked in tincture of iodine, and allowed to dry. Some milk should now be drawn from the teat which is again painted with iodine. The needle attached to the aspirator (all the air being previously expelled from the cylinder) should now be carefully inserted into the teat as far as it will go, the stop cock in them turned on, and when a sufficient quantity of milk has been collected, should be turned off. If desired the milk is collected from the other quarters in a similar manner. The stop cocks securely fixed, the needle and pump may now be removed, and the cylinder brought intact to the laboratory. The contents may then be evacuated by placing the cylinder on its end in a measure glass and opening both stop cocks.

STERILIZATION.

As it is essential these instruments should be sterilised before and after use, they are so constructed as to resist a very high degree of heat. The milk aspirator for ordinary practical purposes will only require boiling. In the lung puncture syringe a higher temperature may be necessary, for here it may be brought in contact with material used for incubation purposes, in which case a higher temperature than boiling point is required. Where dry heat is used a gradual rising temperature from the normal up to 130 degrees centigrade may be applied, and in the case of moist heat a slightly higher temperature may be used. Owing to the unequal expanding powers of metal and glass, it is needless to add the piston should be removed from the syringe and the metal flanges from the aspirator, in fact all disjoinable parts should be separated.

The instruments are made at my request by Messrs. Arnold, Giltspur Street, Smithfield, London.

WM. SCOTT, F.R.C.V.S.

ABSTRACTS FROM FOREIGN JOURNALS.

PHLEBITIS ORIGINATING FROM STRANGLES AND RESULTING IN SEPTICÆMIA.

Natal records (*Journal de Méd. Vét. et de Zoot de Lyon*) the case of a four-year-old gelding, which showed an uncertain and dragging method of progression.

The right hind limb was brought forward with difficulty; it was warmer and a little more voluminous than the left; and palpation of it caused pain and left a slight resultant depression. The rectal temperature was 104.5° F.

There were traces of old contusions, entirely cicatrised, upon the hock and cannon regions, but not the least wound.

Upon examination, very localised but very distinct signs of pulmonary congestion were found at the *right* side of the chest. At this point there was a slight dullness and a blowing sound.

The sounds of the heart were dull, ill-defined, and unequal in force, indicating a little myocardiac insufficiency. There was also a little tachycardia.

The palpebral conjunctiva was cyanosed, and the appetite was completely lost.

The diagnosis reached was that of phlebitis of the right limb, with consecutive embolism, which had caused an infarct of the right lung.

The cardiac symptoms were disquieting. The irregularity and muffling of the cardiac sounds, with the tachycardia, indicated enfeeblement of the myocardium and suggested an infectious generalisation, which was already indicated by the pulmonary infarct.

The horse was bled to the amount of five litres (= about 8½ pints). Further treatment consisted in saline purgation, the application of mustard to the chest, the administration of digitalin and caffeine, and moist local dressings.

At the end of four days the temperature had fallen to 102.2° F., the pulmonary symptoms showed a distinct amelioration, and a slight improvement in the general condition appeared to be produced. But the heart continued to show the same feebleness, while the engorgement of the cannon and hock increased, despite all care, and rose upwards.

Three days later the local symptoms became disquieting. The horse remained lying most of the time, and in the rare and short intervals of standing he bore no weight upon the affected limb. The local sensitiveness and pain increased. The finger left a very deep impression in the œdematous regions.

This condition remained stationary for a few days, and then grew worse. Fistulæ opened upon both the anterior and posterior roots of the internal saphena vein, and after the external saphena, giving exit to a thick creamy yellow pus, manifestly pertaining to strangles pus. The pus was streaked with blood, and sometimes pure blood flowed away.

The horse now collapsed very rapidly, and died fifteen days after the first examination.

It seems clear that the animal died of septicæmia, the pathogeny appears easy to establish. The infection of the blood had occurred from microbial emboli proceeding from the phlebotic area. The horse had been one of a lot of strangles patients, and the pus from the fistulæ had the characters of strangles pus. Strangles streptococci, therefore, had invaded the blood stream. Under the influence of contusions—the animal being infected with strangles—strangles abscesses were formed in the more or less immediate neighbourhood of the saphena veins, and the latter had gradually been invaded by the infection, causing phlebitis and then septicæmia.

Post-mortem, the chief interest lay in the condition of the right hind limb. It was the seat of an enormous enlargement, especially marked upon the leg and thigh. Above the hock on the inside were two fistulæ which, upon the least pressure, discharged yellow creamy pus streaked with blood. A symmetrical fistulous opening existed on the outside. The internal fistulæ were connected with the anterior and posterior roots of the internal saphena vein, and the external one with the external saphena and the gastrocnemius. The tendon of the gastrocnemius was undergoing mortification, and was bathed in pus.

The internal saphena vein was thrombosed, forming a hard resistant cord. Its walls were "transformed into a pyogenic membrane," and contained a purulent liquid mixed with blood clots. It presented these characters as far as the region of the two adductors of the leg, where it was finally obliterated by a large blood clot. The femoral vein which continued it was healthy. The muscles of the limb had the aspect of congealed meat, and were strewn with miliary abscesses containing very thick pus.

There was nothing noteworthy in the lung apart from hypostatic congestion, and one portion a little darker than the rest, which appeared to be the centre of the embolism.—*Annales de Méd. Vét.*

CHRONIC PYOMETRITIS IN A COW.

Herbet records (*Journal de Méd. Vét. et de Zootechnie de Lyon*) the case of a sterile cow, ten years old, which for several years had shown symptoms of abdominal pains. During the latter part of the time her appetite had become capricious.

Upon examination, Herbert discovered chronic peritonitis with effusion; but was unable to determine the origin of the condition. The cow died the next day.

Post-mortem, the uterus was found to be of enormous size. The inferior and median part of the body of the uterus showed a black ecchymosed portion, with a large opening at its centre. This opening was circular in one-third of its extent and almost rectilinear in the remainder.

Pursuing the examination of the uterus, Herbert found that its internal face was destitute of cotyledons, and that it had never possessed an opening giving access to the vagina. The vagina itself, which was thus a veritable *cul-de-sac*, was extraordinarily capacious.

The histological study of the uterine wall revealed lesions of chronic purulent metritis.

The rupture of the inferior wall of the uterus may be explained by the distension and thinning exercised by the abundance of exudate accumulated in the uterine cavity. Perhaps a traumatism or some effort may have encouraged the rupture. The actual cause of death was secondary peritonitis.—*Annales de Méd. Vét.*

GIANT-CELLED SARCOMA OF A DIGIT.

The giant-celled sarcoma, which develops exclusively upon bone, is not a common tumour in animals. Its rarity in the digital region has led Ball to record (*Journal de Méd. Vét. et de Zootechnie de Lyon*) the following case.

The subject was a cat, six years old. The right fore foot appeared voluminous as a result of the presence of a rounded tumour the size of a walnut in the region of the fourth digit. At the summit of this neoplasm was a small ulcerated prominence, reddish and granular upon its surface, and covered in places by scabs.

The skin was adherent to the neoplasm. The hairs had disappeared upon the summit of the lesion, around the ulceration.

The consistence of the tumour was firm. Upon section the tissue showed a lobulated structure, a greyish colouration, and a very vaguely hyaline aspect. The lobules measured from a few millimetres to one centimetre in diameter, and were united by a very fine framework of connective tissue. Some lobules were soft and hæmorrhagic.

By its progressive development the tumour had caused the separation of the third and fifth digits, the claws of which flanked the neoplasm laterally.

Histologically, the tumour showed the characters of a giant-celled sarcoma.—(*Annales de Méd. Vét.*)

(Nothing is stated of the history, or whether treatment was attempted.—*Transl.*)

W. R. C.

THE BROWN INSTITUTION.

The annual report of the Superintendent of the Brown Animal Sanatory Institution (Mr. F. W. Twort) has been received by the Senate of the University of London. The Institution was founded under the will of the late Mr. Thomas Brown, who died in 1852, for the purpose of "investigating, studying, and without charge beyond immediate expenses, endeavouring to cure maladies, distempers, and injuries any quadrupeds or birds useful to man may be found subject to." The report states that in the year 1913 the total number of examinations of animals made was 7,036, and the total number of animals brought to the Institution was 6,022, of which 565 were in-patients at the hospital. Animals under treatment included 3,956 dogs, 1,355 cats and 535 horses, the commonest diseases being distemper, mange and scabies in dogs, and lameness in horses. It was estimated that 400 animals were sent away to veterinary surgeons treatment being refused on the grounds that the owners could afford to pay the proper fees. Of the 565 in-patients, 520 were cured or relieved, 17 died, and 28 were destroyed as incurable. The research work of the laboratory attached to the Institution included investigations on the thyroid gland, John's disease, tuberculosis, leprosy, and infantile diarrhoea, the last investigation being carried out for the Local Government Board.

UNIVERSITY OF LONDON.

REPORT OF THE SUPERINTENDENT OF THE BROWN INSTITUTION FOR THE YEAR 1913. [ABSTRACT.]

PREMISES AND STAFF.

Through lack of funds it has been found impossible to replace the old zinc shed and wooden hutches which are used for rabbits, guinea-pigs, and other small animals, and it has been found impossible to replace the old operating shed.

As has been pointed out in previous reports the roof of the stables needs re-slating, and I am of opinion that it would be advisable to place electric light in the house, also to cut off with a tap the network of gas pipes under the laboratory and to place a new straight pipe in the laboratories.

LABORATORY.

The five lectures required to be given under the will of the late Mr. Brown were delivered during December in the theatre of the Royal College of Surgeons, and I wish to thank the Council for allowing me the use of the theatre. The subject of the lectures was "The Cultivation of Animal and Vegetable Micro-organisms."

During the year a number of pathological and bacteriological examinations were made on materials which were obtained from the hospital. Other investigations have been carried out in the laboratories by different workers.

MR. W. EDMUNDS.

(1) *The functions of the Thyroid and Parathyroid glands.* Mr. Edmunds has continued his investigations on the thyroid and parathyroid glands; the experiments had relation to the functions of these glands, and to the nature of exophthalmic goitre in man. The experiments were performed on dogs.

PROF. T. HEWLETT AND
DR. J. A. SHAW-MACKENZIE.

(2) *Serum tests for malignant growths.* Professor Hewlett and Dr. Shaw-Mackenzie have carried out some experiments on certain serum tests for malignant growths.

DR. C. C. TWORT (Beit Memorial Fellow).

(3) *Production of Johne's disease in Rodents.* Dr. C. C. Twort has carried out a number of experiments with Johne's bacillus and small animals, and by the use of a strain of Johne's bacillus which had been acclimatised to grow on ordinary glycerine-beef broth, has infected rabbits, rats and mice. He has shown that the bacilli do not multiply at the site of inoculation but, as in ungulates, select the lymphatic glands and intestinal mucosa for their further development. The disease produced in these animals is practically identical with that found in naturally infected cattle and sheep.

(4) *Coccidium oviforme and coccidium bovis.* This investigation was undertaken to determine whether or no these coccidia are identical; the work is being continued.

(5) *The rapidity with which lymphatic glands become infected.* The results of this investigation demonstrate that when micro-organisms are inoculated into the peritoneal cavity of animals, the lymphatic glands in the thorax become infected within five minutes after the intraperitoneal inoculation. The same result was obtained with all the micro-organisms tested; these included tubercle bacilli, Johne's bacillus, staphylococci and other cocci.

(6) *Immunity in tubercular disease.* This investigation is being conducted to determine the relation between the caseation of tubercular tissues and the rise of temperature produced by the inoculation of a vaccine or by an auto-inoculation. A considerable number of experiments on the test tube immunity reactions in tubercular disease and in Johne's disease are also being carried out.

THE SUPERINTENDENT.

(7) *The cultivation of the lepra bacillus of rats.* These experiments have been continued, and I have attempted to grow this bacillus on a number of fresh media and under various conditions. All the results were negative.

In addition to the experiments related above, I have carried out several investigations conjointly with Mr. G. L. Y. Ingram, with Dr. Mellanby, and with Dr. C. C. Twort. These experiments were as follows:—

With Mr. INGRAM.

(8) *Johne's disease of cattle.* We have continued our experiments on this condition and have shown that (i) the disease may extend to the lymphatic glands outside the abdominal cavity, (ii) the disease in sheep is identical with the disease in cattle, and is produced by the same bacillus, (iii) diseased sheep react to a diagnostic vaccine of Johne's bacillus in the same way that cattle react, (iv) Johne's bacillus, besides growing on media containing other acid-fast bacilli, or extracts obtained

from them, will also grow on media containing extracts obtained from certain vegetable substances: these include the chloroform soluble portion of an alcoholic extract of crushed fig seeds, an alcoholic extract of certain fungi such as *Cantharellus aurantiacus* Fr., an alcoholic extract of certain seeds such as linseed, etc. These results confirm the suggestions put forward in our previous papers and in our "Monograph on Johne's disease."

It may be mentioned here that the work carried out on Johne's disease at the institution since the beginning of 1910 has been published in fourteen parts, as papers in different journals, including those which have been accepted for publication but have not yet appeared. The work to the end of March, 1913, was included in a monograph on Johne's disease which we published in April.

With Dr. E. MELLANBY.

(9) *Infantile diarrhoea.* This investigation is being carried out for the Local Government Board. During the past year we have isolated and tested a number of bacilli, and have carried out a considerable number of experiments to ascertain the conditions which determine the absorption of toxic substances from the intestinal tract. The work is being continued.

With Dr. C. C. TWORT.

(10) *The nature of certain filter-passing micro-organisms.* This investigation is also being carried out for the Local Government Board.

HOSPITAL.

The total number of examinations made was 7,036, and the total number of animals brought to the Institution was 6,022. In addition to these probably 400 animals were sent away to veterinary surgeons, treatment being refused on the grounds that the owners could afford to pay the proper fees.

The actual numbers of the various animals were as follows:—

Species.	Out-Patients.	In-Patients.
Horses	535	136
Asses	25	2
Goats	5	3
Dogs	3956	289
Cats	1355	125
Poultry and other Birds	122	5
Rabbits	22	4
Monkeys	2	1
	6022	565

Operations, etc.	Cured or relieved.	Died & cause of death.	Destroyed incurable.	Total.
Abscesses	48	5 Pneumonia	3	56

5 Diabetes insipidus	D 5.

F. W. TWORT, Superintendent.

March 13th, 1914.

LINCOLNSHIRE

VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

A meeting was held at the "Angel" Hotel, Peterborough, on Thursday, June 11th. Mr. C. W. Townsend, F.R.C.V.S., of Long Stanton, the President, in the chair. Also present : Messrs. T. Hicks, Sleaford, Hon. Sec.; T. B. Bindloss, Long Sutton; F. L. Gooch, Stamford; Geo. Lockwood, J. Mackinder, Peterborough; A. Lennox, Crowlands; W. W. Lang, Ulceby; H. H. Nichols, Oundle; J. H. Poles, Whittlesea; T. A. Rudkin, Grantham; and H. C. Taylor, Caistor.

A telegram was received from Mr. W. A. Allott, Upwell, regretting inability to attend.

The minutes of the February meeting were taken as read.

PETROL TAX AND JURY SERVICE.

Mr. BINDLOSS said that by the minutes he saw that it was stated by a member at the last meeting that veterinary practitioners were free from the petrol tax and jury service—was that so?

The HON. SEC. said that was not correct. They were not exempt from the petrol tax, but they said they ought to be.

Mr. GOOCH said they would not let him off the petrol tax, even as a tradesman. As to jury service the only way to get off was to see the overseer and get him to mark them as not eligible.

Mr. BINDLOSS : The overseer is liable?

Mr. GOOCH : No. I claim exemption as a medical man.

Mr. BINDLOSS said jury service did not affect practitioners in town so much as in the country, and if he were summoned to Lincoln Assizes for Monday he had to go overnight.

The CHAIRMAN: You are not exempt then?

Mr. BINDLOSS: No. I have tried to get off at Spalding Quarter Sessions, but without avail.

Mr. GOOCH said that they would be exempt under the Charter of the Royal College now before Parliament.

The HON. SEC.: If that becomes law it will relieve us of service.

Mr. GOOCH: Yes.

THE INTERNATIONAL CONGRESS.

Sir Stewart Stockman wrote asking the Association to appoint a member to represent them at the International Congress in London from the 3rd to the 8th August.

On the motion of Mr. Hicks, seconded by the President, Mr. F. L. Gooch was unanimously appointed a delegate, and it was decided to send the necessary subscription of £1.

Mr. GOOCH returned thanks for the honour done him, and said he should be glad to hear from members who had not subscribed to the entertainment of their foreign visitors. The sum of £79 2s. had been promised, and he had received to date £69 6s. and he should like to make it up to £100.

THE LATE MR. WM. HUNTING.

The President of the Royal College wrote asking the Association to assent to the petition to the Treasury for a pension to be granted from the Civil List to the children of the late Mr. Wm. Hunting.

The CHAIRMAN: I am afraid the petition has gone to the Treasury.

Mr. GOOCH said one had been sent in, but they could send another to Mr. Gray as suggested in the letter.

The CHAIRMAN said it was a most deserving case, and no one was more generous in forwarding the work of the Association than Mr. Hunting.

Resignation. The resignation of Mr. Andrew Young, of Chatteris, was accepted.

DEATH OF A MEMBER.

The President said he regretted to have to record the death since their last meeting of Mr. Howse, of Lincoln, one of their oldest members, and indeed one of the founders, he believed, of the Association. He moved a resolution of condolence with his relatives.

Mr. RUDKIN: I knew him before I joined the profession; a nicer man or a better professional friend I never knew. He has no relatives, but I should like it recorded on the minutes that he was "one of the best."

The HON. SEC.: Out of respect for the profession, his housekeeper gave me an intimation of his death.

Mr. MACKINDER: He was present at our first meeting, at Louth.

The resolution of regret was carried, all standing, and ordered to be entered on the minutes.

FEES FOR EXAMINATION.

A scale of examination fees adopted by the National Veterinary Medical Association, and forwarded by Mr. Theo. Toope, of Dover, was adjourned for consideration to the next meeting.

SOME INTERESTING CASES.

By W. W. LANG, M.R.C.V.S.

At our last two meetings we have had what I might describe as more advanced though quite desirable subjects, viz., "The method of milk examination for tubercle bacilli" by Mr. Lewis, and a paper with demonstration on "Abdominal Surgery in the Dog" by Professor Brayley Reynolds. Now, I trust it is no retrograde movement on my part to return to the more common experiences of our everyday life and give you a paper on what we all more or less meet in our ordinary practice.

DYSTOKIA: OPERATION.

My first case hardly needs the above description because it bears on Professor Reynolds' paper. Curiously enough, just a week after, I had a case of dystokia in a very small Yorkshire terrier. She was not due to whelp till the end of the week, but evidently a long motor ride from Kent to North Lincolnshire on the Monday had upset her, for about 7 p.m. the same evening she became uneasy. I was called in the following night about 9 p.m., and on examination could feel the nose of the foetus at the entrance to the pelvis. As the bitch was so small I could do nothing by manual manipulation and as the foetus appeared normally placed I gave her, to begin with, 5 minims Pituitrin, which very shortly caused a good deal of discomfort and uneasiness. No progress was made so I repeated the Pituitrin, giving larger doses up to 1 c.c. but while there was no doubt of the action of the agent it was now (11 p.m.) apparent that nothing short of an abdominal operation was indicated. Accordingly I had her brought to my place next morning early, and with the assistance of Mr. Taylor the operation was carried out.

We gave about $\frac{1}{2}$ gr. morphia (perhaps rather much) without chloroform, and as soon as anaesthesia was complete we commenced. On reference to Prof. Hobday's book I found the remark that in such cases as large an incision as is necessary should be made. You will realise on hearing the following how large that abdominal opening was.

The first organ to come into view was a very much distended bladder; for the moment I wondered what it was. We attempted to pass a catheter, but soon realised this as a dangerous if not impossible procedure. The difficulty was overcome by tapping the organ with a hypodermic needle and drawing off the urine. When we got to the uterus, which appeared normal in colour, we found only one puppy, a very large one, and, as we afterwards discovered, emphysematous. The abdominal wound had to be considerably enlarged to allow of ligaturing the ovarian vessels and detaching the ovary and horn. After repeating this part on the other side we found that the nose of the foetus was jammed in the pelvis—this accounted for the state of the bladder—while the hind parts were closely pressed against the ovary, and that it was impossible to withdraw the puppy to allow of ligaturing the uterine neck. To overcome this we held the ovarian end of the horn well away from the abdomen, incised it, and pulled the foetus out altogether. The rest of the operation was as usual—ligature of the neck, sterilization of the stump and suture of the now enormous abdominal wound.

The operation took place about 11 a.m.; the bitch recovered consciousness about 7 p.m. and took an interest in things, but about 10 p.m. she commenced to collapse and died at 1.30 a.m., no doubt from shock.

I am informed that in human surgery the operation, after labour pains have commenced, is nearly always fatal. Altogether I think we had bad luck in our first case. We feel satisfied that so far as the operation is concerned it was quite all right though we seemed a long time over it.

Here I may mention a point in connection with Prof. Reynolds' paper on Inguinal hernia. In man, I understand, a method of operating which finds favour is to push the forceps through the internal oblique muscle, seize the hernial sac at its apex and draw it through until comparatively taut, ligature and stitch the stump to the fascia. You may wonder, as I did, whether there is any likelihood of recurrence, but the answer is in the negative, though one would naturally expect that in a successful operation by ligaturing the sac over the ring in the ordinary way a larger swelling with subsequent cicatricial contraction would prove a more formidable barrier to any subsequent prolapse of the bowel.

I can understand that we may sometimes be called upon to operate on the male, but not castrate—the two are usually carried out together in our patients—in animals specially valuable for breeding purposes, and I think the above method may with advantage be tried. In our patients, however, it might be more advantageous to stitch the stump to the muscle itself for greater security. When the sac is not drawn as tightly as required a stitch is inserted to bring the canal to its normal size.

DOUBLE MEDIAN AND ULNAR NEURECTOMY.

Some years ago I bought a weight-carrying cob which had been used as a polo pony. As was to be expected he was rather full in the legs, if I may use the phrase, but as I got such a good character with him I risked him. He did very well in harness for a bit, then began to go short. Rest improved him, but work undid him again. I diagnosed ostitis, and, accepting the late Mr. Hunting's statement that there is no cure, decided to unnerve. I had had practically no experience of the operation, so, after concluding that the internal aspects of his fetlocks were more at fault, I operated on the internal plantars only—but without success. At this stage I severed one of the arteries, and although there was no really bad after effect, that part used to fill up considerably while the animal stood in a stall and go down again with exercise. An interesting point here is that until it had filled up it always "sweated." About that time I got into communication with Mr. Willis, of London, who generously advised me, saying that in all cases of lameness at or above the level of the fetlock median neurectomy was required, and that in my case probably both median and ulnar neurectomy would be necessary. He was quite right; after the animal recovered from the median operation work soon proved the necessity for the ulnar, which was done some time in May. In a few days, from want of experience, I was rather startled on finding that the hoof had separated from the skin on the inside heel of one foot, but this proved to be a false alarm; the condition had evidently been caused by struggling in the hobbles.

From that time onward he worked as well as possible though I set up ostitis on the off fore leg by working him hard in order to get him accustomed to motor traffic. Bandaging and a few days' rest soon put that right.

Many, when I have told them, have expressed the greatest surprise that with perfect safety I drove, hacked, and hunted this cob from the beginning of the cubbing season till the end of the following February. I knew no difference between him and a sound horse. Gentlemen, don't imagine I was reckless to a degree, for I tried him hacking and jumping before I hunted. All went well till one day when galloping across a field one of his legs went "flippity flop," just as if he had a leg over the rein, when I pulled him up—he did not fall. When he put weight on the leg down went the fetlock and up went the toe, so I destroyed him at once. I had suspected a slight returning sensation, though he was insensible to pin pricks, but after the leg gave way he appeared to have no pain, alternately grazing and listening to hounds till he was shot.

Post-mortem examination revealed complete dislocation of the fetlock joint, the suspensory torn off the sesamoids, these bones themselves forced from their attachments, and all tissues separated from the lower end of the metacarpus to the extent of 3-4 inches. Neither of the flexors was ruptured, and all the severed nerves had reunited, though I had removed from $\frac{3}{4}$ inch to 1½ inches.

These are the bones from both knees downwards; there are signs of ostitis, but the chief interest lies in the sesamoids, which are all diseased, the external sesamoid of the near fore least so. The grooves parti-

cularly show necrosis, and I think the thickening of the fetlocks at that situation was Nature's effort at compensation. Why is the external sesamoid on the near fore comparatively healthy? What is the cause of the trouble, sprains or blows, brushing for the inside two and blows from the polo stick for the external sesamoid of the off fore? He was perfectly straight in action, but we all know what polo is. I shall be glad to have your opinion.

A FEW ABDOMINAL CASES.

This is a very wide subject, quite incapable of being fully discussed to-day, so I purpose mentioning and discussing only a few cases which I have met in practice. I do not possess the book on Colics by Mr. Caulton Reeks—the loss is probably mine—but with the coming of Hutyra and Marek my interest has been considerably quickened. I hold the opinion that no one has a greater contempt for his own powers of differential diagnosis than I; we have all heard of such a symptom being diagnostic of such-and-such a condition, but I sometimes have very great difficulty. Hutyra and Marek state that in many cases there is no diagnostic symptom, and at the same time they attach a great deal of importance to rectal exploration. In my earlier days this was confined to unloading the rectum preparatory to giving an enema; then when I came to North Lincolnshire and met so many cases of impaction I confirmed my diagnosis in this way.

In the following short list I hope to illustrate the diagnostic difficulties and at the same time to draw attention to the importance of rectal exploration; correct diagnosis in this way, according to Major-General Smith, necessitates a thorough knowledge of the physiology and anatomy of the abdomen, and I fully appreciate that statement.

DRAPHRAGMATIC HERNIA.

(1) This case occurred a few years ago so I do not remember all the symptoms shown. Suffice to say the horse was at grass when taken ill, and the chief characteristic was vomiting of clear gastric fluid at short intervals for 20 hours before death; the animal stood practically still all the time. Post-mortem revealed a small hole in the diaphragm through which about six feet of the small bowel had found its way into the thorax. There was a fair amount of cicatricial tissue, apparently of recent origin, round the hernial opening, so we concluded that it was something of the nature of a perforating ulcer.

The next two cases were similar in some respects; the animals did not die, but I should like to know what was actually wrong.

(2) Gelding: taken ill at 10 p.m., saw him at 3 a.m., considerable abdominal pain, sweating profusely, pulse over 80, belching at short intervals—this continued for 12 hours. Examination per rectum revealed the small bowel considerably distended, but all the rest appeared normal. *Diagnosis:* Twist—strangulation is a better term. *Prognosis:* Death.

I attempted to pass a rubber tube to relieve the gastric tympany, but without success as my tube was not long enough. There was no difficulty in handling the animal and inserting the tube as far as possible. As the horse had already received two colic draughts and a pint of linseed oil, I contented myself with giving hypodermically a strong dose of morphia and atropine, but this had little effect. The owner promised to report, so about 9.30 a.m. a telegram was received stating that the horse was still alive but very bad; about 11 a.m. another wire, "Come to horse." I was agreeably surprised to find the patient much better, and was informed that shortly before he had had a very rough time.

(3) Mare: taken ill at 8 p.m.; called to her at midnight. Pulse 44, uneasy, sweating, getting up and

down, peristaltic action excessive, but no gastric symptoms, no belching; passing faeces in small quantities but no flatus; rectum empty, but not dilated; small bowel much distended as in previous case. Had received the customary oil and three colic draughts.

10 a.m. Pulse 60, still no motion or flatus; went on with stimulative treatment.

8 p.m. Pulse 96, and very weak, prognosis death, wished to perform laparotomy, but was refused permission. Gave a warm enema only. Within half-an-hour peristalsis increased again, and recovery was uninterrupted. The pain in this case was continuous for 24 hours.

TWIST OF THE DOUBLE COLON.

In the next two cases the cause of death was complete torsion of the double colon at its base.

(1) Mare: pulse about 80, and very weak, pain not violent but continuous; animal lay quiet for considerable periods. Rectal exploration satisfied me that the double colon was considerably displaced as I could not locate the pelvic flexure. Diagnosis: twist. The owner was willing, so I chloroformed and examined the abdominal contents through an incision in the roof of the vagina, but that proved unsatisfactory; the mare was too long for me to reach the seat of the trouble. Post-mortem as above.

(2) Mare: very violent, sweating profusely, passing liquid faeces: examined per rectum, but without any satisfaction as she was dangerous to the operator. Had oil and colic draughts as usual, so gave anodynes per os and hypodermically, but without effect. Post-mortem showed a condition similar to the preceding case.

Note the difference in the amount of pain and duration of illness; the second animal died in six hours less than the first, and still the pathological condition was the same as far as I could see.

MESENTERIC TWIST OF SMALL BOWEL.

Mare taken ill at 1 p.m.: saw her in a dying condition at 7 p.m. On rectal examination I found the twist, but could not satisfy myself as to its true nature. As dissolution was imminent I saw no use in attempting an operation.

Post-mortem confirmed my diagnosis; the twist came undone quite easily. I consider this quite a suitable case for laparotomy, and I believe the trouble could have been rectified through a vaginal incision, though I would not hesitate to operate through the flank.

TWIST OF FLOATING COLON.

When seen this patient was rolling about in great agony. I examined her while still rolling on the floor and found the bowel spirally twisted. I reached in as far as possible, seized the longitudinal band, gently pulled it back to the anus and released it. Reinserting my hand I found the bowel apparently all right; pain ceased immediately, so I tested my opinion by giving no further medicine or other treatment, except a heart stimulant hypodermically. Three days later when taken to work for the first time she was taken ill and died before I got to her. Post-mortem showed the same part of the colon twisted round its long axis. I wondered why there should be a recurrence, but I see that Major-General Smith says the most common cause of abdominal trouble is work.

With reference to differential diagnosis this appears to be very difficult at times. It does not satisfy me to treat all cases in a routine fashion? we all know perfectly well that to get the best results we must treat each case on its merits.

The first case mentioned was, of course, strangulation due to the hernia. Take the two following; what were they? Evidently strangulation, but of what and how?

Had these horses been my own I should have operated, but after events proved that I should not have been justified. Major-General Smith states that the most common cause of death from abdominal diseases is *strangulation*, while Hutya and Marek state that spontaneous recovery from strangulation rarely if ever occurs, and that medicinal treatment is useless.

Possibly the success of stimulative treatment is attributable to the fact that the bowels are kept on the move and thus may extricate themselves. There is quite a formidable list of causes of strangulation in Hutya and Marek: congenital diverticula of the ileum, acquired diverticula of the intestines, ligament between the kidney and spleen, spleno-gastric ligament, falciform ligament of the liver, urachus, small omentum, pediculated neoplasms (generally lipomata), exceptionally pediculated lobes of the liver, stump of spermatic cord, cord of undescended testicle, larger omentum, etc.

Have we in the past been minute enough in the examination of our colic cases? Have we tried as we ought to make a differential diagnosis—and when we have decided what is wrong, what about our treatment? Take for example tympany and impaction of the stomach in the horse. Are we justified in treating these conditions medicinally after the description of the use of Marek's stomach catheter? And if, when satisfied that there is strangulation or twist, why not kill your patient in an honest endeavour to save his life by laparotomy? I think most of my clients would agree, as several have already told me that the horse can only die then. We are apt to forget that we are "veterinary surgeons" not mere "veterinary medicine vendors." Instead of complaining of the medicines sold to our clients—and this is generally useless—we have the opportunity of proving in some cases at least that operative interference is much more efficacious than drugs.

For my own part I should have little fear of laparotomy, not because there is no danger, but because we know that with proper precautions we can take a good deal of liberty with the abdomen and its contents. In my earlier days of rig castration I have often pulled out a piece of the bowel thinking it might be the testicle, and if my memory does not trick me, I believe I have read that Prof. Macqueen, when unable to find the missing organ through the inguinal canal, has located it through the rectum, washed his hand and arm, and carried on the operation in the usual way. I should not like to risk that myself. Then again, some of you at least would see for yourselves in one of the recent journals that Mr. Winter, of Limerick, prefers operating on rigs through a flank incision.

This concludes my paper. If I have kept up the object of these meetings, that of stimulating the interest of the members, I shall feel amply repaid. Should any of you consider anything controversial I trust you will not hesitate to express your opinions. No criticism can be too severe for me, I shall welcome it, and other views, for these are all required that we may get at the truth.

An interesting discussion followed.

The President said he was sure they were very much indebted to Mr. Lang for giving them such an excellent paper on short notice, as a week before they did not know who to look to for one. Unquestionably they could learn much by recording their cases in daily practice.

Mr. Gooch proposed a vote of thanks to Mr. Lang for giving them a paper which they, as country practitioners, could fully appreciate. He thought if more country practitioners attended their meetings there would not be such things said as they now heard in the law courts. He did not remember a meeting he had

attended where he had not learned something. The best knowledge was the knowledge of experience. We may read text-books, but the best teacher is practice. He thought their best thanks were due to Mr. Lang for his paper.

Mr. MACKINDER seconded, remarking that such practical essays as that which Mr. Lang had given them were better than theoretical papers, all learnt by experience, and he would remind them that the maxim "*experientia docet*" is an old one.

Mr. LANG, in returning thanks, said he had never known a discussion which so closely followed a paper.

On the motion of Mr. Rudkin, seconded by Mr. Lennox, a hearty vote of thanks was accorded the Chairman; the members then adjourned for high tea.

Prosecution under the Tuberculosis Order.

In the Midlothian J.P. Court on Tuesday, 9th inst., Arch. Colthart, Cameron Park Dairy, Craigmillar, was charged that, on 29th April, he had in his possession a cow which was, or appeared to be, suffering from tuberculosis of the udder, or indurated udder, and that he did fail to give information to the proper authority in terms of Article 2 of the Order. He pleaded not guilty.

In the evidence, Mr. John Riddoch, veterinary inspector for the City of Edinburgh, said he had visited the accused's dairy, and had had his attention drawn to this particular cow. He suspected from the appearance of the udder that it was tuberculous, and when a sample of its milk was examined under the microscope he found

that it contained tubercle bacilli. The cow was ultimately slaughtered under the Tuberculosis Order.

The milk from the cow was being supplied in the City of Edinburgh, and the matter was at once brought under the notice of Dr. Williamson, the Medical Officer of Health. Witness was of opinion that the animal had been in that condition for several weeks.

Mr. John Taylor, veterinary surgeon, and one of the veterinary inspectors for the County of Midlothian, said he had also examined the cow with Mr. Riddoch, and he confirmed the latter's opinion that the animal was tuberculous. The whole trouble about this matter was that dairymen did not appreciate the fact that they had simply to notify a police constable or a veterinary inspector when they noticed anything suspicious about a cow's udder. A tuberculous udder might give milk that was perfectly clear, and the tubercular qualities might not be detected until it was put under the microscope, but if dairymen would but warn the proper authority about any suspicious development of the udder, there would be no prosecution. It was the failure to notify which constituted the offence.

The accused, in the witness-box, said that the cow had been milking very heavily, and there did not seem to be anything to indicate that she was suffering from tuberculosis. He thought she was merely suffering from a fleshy udder. He was satisfied now that the cow had been tuberculous.

It was pointed out that this was the first case of the kind in the county, and the Bench made the fine one of £2, with the alternative of 20 days' imprisonment. The maximum penalty is £20.—*N.B.A.*

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, June 15, 1914
NOTE.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

Congress of the Royal Sanitary Institute.

The preliminary programme of the twenty-ninth Congress, to be held at Blackpool, from July 6th to 11th has been issued.

The Conference of Veterinary Inspectors will be held on Wednesday, July 7th, at the Secondary School.

The subjects for discussion will be:—

"Some Metazoon Parasites met with in Food Inspection and their relation to Public Health," to be opened by A. W. Noel Pillers, F.R.C.V.S., Veterinary Inspector, Liverpool.

"The Working of the Tuberculosis Public Health Regulations of the Local Government Board and Board of Agriculture," by J. D. Whitehead, F.R.C.V.S.

President. J. W. BRITTLEBANK, M.R.C.V.S., D.V.S.M., Veterinary Inspector, Manchester.

Vice-Presidents. ARTHUR BREAKELL, M.R.C.V.S.; JAMES R. RIGBY, M.R.C.V.S.; J. SHARE-JONES, M.Sc., F.R.C.V.S.; T. WOODS, M.R.C.V.S.

Local Secretaries. G. HUTCHINSON, M.R.C.V.S., Poulton le Fylde; T. WALKER, M.R.C.V.S., Whitegate Drive, Blackpool.

Recording Secretary. J. A. DIXON, M.R.C.V.S., Vety. Inspector, Leeds.

This Conference is open to members of the veterinary profession.

R.S.P.C.A. Prosecution at Bourne—Dismissed

At the Bourne (Lincs.) Police Court, on Thursday May 14th, before Mr. R. A. Gardner, J.P. (in the chair), and other Justices, James Bluff, drayman, of Stamford, was charged with cruelty to a horse at Market Deeping, on April 2nd; and Richard Dunn Dawson, manager of Messrs. Phillips Brewery, Stamford, was summoned for causing the animal to be worked whilst in an unfit state. Mr. S. G. Polhill, of London, represented the Society, and Mr. E. Dalton, of Stamford, defended.

Both defendants pleaded not guilty.

Mr. Dalton stated that it might save the time of the court if he stated what the defence would be. The mare started on its journey in a perfectly sound condition, but on its return journey it was suddenly attacked with a complaint called laminitis.

All the witnesses were ordered out of court.

Mr. Polhill, in opening the case, said the animal belonged to Mr. Phillips, brewer, of Stamford. On the date in question the mare was stopped by the Society's inspector as it was going very lame. The drayman frankly admitted that the mare was lame, and that it had been so for some time. Mr. Townson, veterinary surgeon, of Market Deeping, was deputed to examine the animal, and he pronounced that the lameness was of long standing. The next day the inspector went to Stamford and Mr. Dawson admitted that he was responsible for the horse being at work, but he would not admit that the horse had been previously lame. Mr. Dawson subsequently suggested to the inspector that this was a temporary lameness, that it left the premises all right in the morning, and that it became lame on its return journey. Proceeding, Mr. Polhill said that it was thought advisable to test this case, and after waiting some three weeks the Society sent down an expert veterinary surgeon from London, and the opinion of the expert and that of Mr. Townson agreed. They would submit that the horse had been lame for some considerable time: that it was not fit to work on the road, and it was extremely doubtful whether it would be able to work on the land. Mr. Polhill said the issue the magistrate would have to consider was whether the lameness was of long-standing or whether as his friend had suggested it was of a tem-

porary nature. He submitted that the weight of evidence would be in favour of the prosecution.

Inspector Small, R.S.P.C.A., stationed in the Bourne district, deposed that he stopped the defendant Bluff at Market Deeping. He spoke to him about the mare going lame, and Bluff replied, "Yes, I know it is going very lame. It has been like it for some time, and the manager knows about it. I have told him several times." Witness said the animal was suffering from ringbone, and one foot was contracted. The animal showed pain, and in his opinion it was unfit for work. Witness said to Bluff, "This is a shocking case of cruelty," and Bluff said, "Yes, it is shocking. I have been ashamed to bring it out." Witness advised the mare not to be worked any further, and it was taken to the stable of an inn at Deeping, and the same day the animal was examined by Mr. Townson. Inspector Small said that the next day he saw the manager, who said that he did not see the horse before it went out, but had seen it in the stables. Witness said in the presence of Bluff to Mr. Dawson that Bluff had said that he had told him of the mare going lame, and the manager denied this. The manager said the horse would not be worked any more.

Mr. Polhill: Have you seen the mare on subsequent dates?—Yes, on the 21st and 24th April, and it was in the same condition exactly.

The Chairman: Have you seen it since April 24th?—No.

Mr. Dalton: There has been no intention to work the horse since that date. Did you make enquiries as to the other horses at the establishment?—No.

Inspector Decann, stationed at Market Deeping, corroborated the evidence given by the previous witness. He said the mare was very lame indeed.

Mr. Polhill: Have you seen this horse before?—Yes, and I noticed it was lame, but did not stop it.

Did you mention that incident to the defendant Bluff?—Yes, and Bluff said that he expected that I should have stopped him on that date.

Mr. Dalton: If you had considered that the mare should not have been worked would you not have called Bluff's attention to it?—I scarcely had a chance of forming an opinion at the time. It was only a casual observation.

There was nothing flagrant about it?—I thought it was, but still I thought it was of a temporary nature.

William Kellett Townson, veterinary surgeon, of Market Deeping, stated that on the 2nd of April he examined the mare in question. He found the animal very lame. She had a deformed hoof, also contracted tendons, with an over-shot fetlock joint and a diseased pastern, associated with ringbone and sidebone. The animal was in good condition. He further stated that the animal was not fit for work: that in his opinion the lameness was of long-standing: that the mare will not be fit for work on the road, nor, in his opinion, on the land.

Mr. Dalton (quoting from a veterinary authority): "Laminitis is a disease which appears suddenly." Do you agree that a horse might be perfectly sound when starting on its journey, but have an attack of this disease whilst on its journey?

Mr. Townson: Yes, and an attack will occur in the stable.

Did you take the temperature of the animal?—No. There was nothing abnormal about the temperature; and the condition of the hoof was not conducive to laminitis.

What percentage of horses suffer from ringbone?—I don't know.

Am I right in saying that 75 per cent. of the horses suffer from it?—I should not think so.

Mr. Polhill: If the contention of my friend is right

that the mare was suffering from an attack of laminitis, which comes on suddenly, would you expect the lameness to remain permanently or would the animal recover?

Mr. Townson: I should certainly expect the mare to recover.

Alexander Piesse, M.R.C.V.S., of London, deposed that he examined the mare at Stamford some three weeks after it was stopped at Market Deeping. The animal, which was a bay mare, was well nourished. He found that the mare was lame, the result of extensive sidebone, the cartilage affected was much affected and inflamed, and the inflammation had extended. There was also a bony deposit on the pastern joint. The hoof was also somewhat malformed. In his opinion the animal was unfit for work. He was quite sure that it would never be fit for work on the road again, but with treatment it might possibly be able to work on the land.

Mr. Polhill: Did you see any signs of laminitis?

Mr. Piesse: No, but it might have had a transient attack: it certainly had not had an attack of any duration. There were no signs that an attack had existed.

Can you form any opinion as to how long the mare had been lame?—I should say that it had not been a sound horse for three months.

Mr. Dalton: When you say that the horse had not been sound for three months do you mean that it had not been in a fit condition for work during that time?—Yes.

Would any ordinary horseman notice that?—No, but he ought to have done in a few days.

Do you think it was possible that a veterinary surgeon could have examined the horse without noticing it?—No.

And supposing a manager did not notice it?—Well, I should say that he has not a keen observation.

I am calling two veterinary surgeons who will say that the mare was suffering from laminitis?—It might have been when they examined it.

Is it a disease that appears suddenly?—Yes.

Mr. Polhill: Would not a horse that had been suffering from laminitis for some time show an unmistakeable alteration of the structure of the foot?

Mr. Piesse: Yes, but it was obvious in this case that it was lame.

THE DEFENCE.

Mr. Dalton said that this mare was perfectly sound when it left the stables at Stamford. He proposed calling two veterinary surgeons who would state that the horse was suffering from laminitis when they examined it, and he hoped to establish this fact and so get the summons dismissed. He said that his friend had got to satisfy the Bench that the defendants had guilty knowledge of working the mare whilst in an unfit state, and also that there was intentional cruelty. No one who knew the firm that he represented could say that they worked horses whilst in an unfit condition. When the mare was in the stable there were no symptoms of lameness, and if there had been there was no necessity to work this horse, for there were others in the stable, and if not they could have hired a horse, which this firm was in the habit of doing when necessary. The defendant Bluff was deputed to take a load to Spalding Common, a distance of about 17 miles. The horse was baited, and upon the return journey it went lame, and the animal was stopped by the Inspector at Market Deeping.

Richard Dunn Dawson deposed that the mare was bought some four years ago at Morton near Bourne, and a certificate of soundness was given at the time of the purchase. The animal had never been lame, and he

had never seen her in pain. Mr. Towell, of Stamford, veterinary surgeon, was specially retained by the brewery firm to look after the horses, and the men employed by the firm had strict instructions that if at any time there was anything wrong with the horses to immediately call in the veterinary. Witness stated that on the day in question he received a telegram from the defendant Bluff that the horse had been stopped by Inspector Small at Deeping on account of lameness, and witness said that he also communicated with Mr. Holmes, veterinary surgeon, of Bourne, to come to Stamford and examine the horse the next day in conjunction with Mr. Towell. The animal was stated to be suffering from laminitis, and it was treated for such complaint.

Mr. Polhill: During the time the animal was developing a bony enlargement did not she go lame?—No.

Do you agree that where a horse is in pain that it must go lame?—Not always.

Do you really mean to say that during the four years you have had the horse that you have never seen it go lame?—I have never seen it go lame. The horse at times had a peculiar gait, but it was never lame.

Although you knew that the animal was developing sidebone, did you not call in a veterinary?—It never went lame.

Has the condition of the mare altered since the 3rd of April?—Gradually improved.

The horse is too lame to bring for the Magistrate to inspect?—It could not have walked.

In answer to Mr. Dalton, witness said the sidebone had never incapacitated the horse.

James Bluff stated that he baited the mare for two hours, and when he commenced on the return journey he noticed that it had a slight stiffness, which was not unusual with horses when they had gone a long journey. However, when within three or four miles of Deeping he noticed the mare went a little lame. When he got to Deeping he saw the inspectors, and the mare was stopped and examined, and he was told that it must not travel any further and it was put up at an inn. Inspector Small said it was a very bad case, and advised him not to go any further.

In reply to Mr. Dalton, witness said the horse had on the previous day been to Barnack and Market Deeping respectively. If he had noticed anything the matter with the mare in the morning he would have refused to take it on the journey.

Mr. Polhill: How long have you driven this horse?—For several months.

At times the animal has shown signs of lameness?—None whatever.

If the animal was not lame why did you speak to Mr. Dawson?—It was not exactly lame.

John Thomas Holmes, M.R.C.V.S., of Bourne, stated that he received a telegram from Stamford to go to Messrs. Phillips Brewery to examine a mare. The animal appeared to be suffering from considerable pain and distress. He took the temperature, which was 103°1, the pulse was 49, and when the mare walked a few yards it showed the characteristic gait of laminitis. The mare had ringbone, but that had nothing to do with the complaint from which it was suffering.

Mr. Dalton: The horse may be worked if it suffers from ringbone so long as it does not cause any pain?—That is my opinion.

Is it not quite an ordinary thing for horses to be suffering from ringbone?—Quite 70 per cent. do in this neighbourhood.

How could laminitis arise?—From several causes, one being chill.

If the animal had been suffering from ordinary acute lameness would there have been any constitutional dis-

order?—No, there would have been no rise in temperature.

Mr. Polhill: You examined the horse on the 3rd of April, and Mr. Townson on the 2nd April, and he says there were no signs of laminitis. Is it possible between the time you examined it and the time Mr. Townson examined it that laminitis might have supervened?—No doubt it supervened.

You don't dispute the existence of ringbone and sidebone?—No.

Have you seen the mare since the 3rd of April?—Last Friday.

What is its condition?—Still lame.

What from?—The effects of laminitis.

If the animal was suffering from laminitis on the 3rd of April must there not have been some structural alteration having taken place in its foot?—It depends entirely on the amount of the disease.

If the horse had ringbone and sidebone and is still lame three weeks after it was stopped by the inspector, is that not a strong indication that the lameness has a permanent cause and not a temporary cause like laminitis?—I don't agree.

During the course of examination Mr. Holmes protested that Mr. Polhill was making suggestions of things which did not exist. Mr. Polhill said he did not think Mr. Holmes need be uncivil. Mr. Holmes repudiated the suggestion of incivility. Considerable argument took place between Mr. Holmes and Mr. Polhill upon the relative terms of stiffness and lameness.

Mr. Polhill: Do you think the mare is fit to work on the road barring laminitis?—Yes I do.

Walter Bland Towell, M.R.C.V.S., Stamford, stated that he was retained by this brewery to attend to the horses when required. He said that when he examined the animal it showed signs of great pain, it moved with great difficulty, was very lame, and was suffering from laminitis. He always considered that the horse was workably sound.

Mr. Dalton: Do you consider that this is a typical case of laminitis?—Yes.

Mr. Polhill: Was the animal perfectly free on the 2nd of April?—Yes.

If the horse had been suffering from a long attack of laminitis and was still suffering on the 24th of April, would any structural alterations of the foot have been apparent to anyone who examined it?—To a certain extent, yes.

Mr. Polhill submitted to the Court that it was not for him to show that there was any intentional cruelty. What the Magistrates were concerned with was the point of fact whether the conduct of the defendants had caused the animal unnecessary pain or suffering. Intentional cruelty was a different thing to guilty knowledge, and the guilty knowledge which was required was not to show that the defendants actually knew that they were causing pain, but the guilty knowledge was the knowledge of the facts. No one was so blind as those who would not see. It was not a defence to say that they did not see it lame. On the grounds he would not say that the defendants had any guilty knowledge but it was a matter of want of care and want of thought, and not of intentional cruelty. It had never been suggested. He said that he could quote cases on the matter.

Mr. Dalton replied that the fact that the firm retained a veterinary surgeon showed that there was no want of care and thought, but showed that they had exercised more than ordinary precaution.

The Chairman, after the Court had deliberated in private, said the Bench were of the opinion that it was a proper case to be brought into Court, but there was an element of doubt in the matter and the case would be dismissed.

Cruelty Prosecution at Bury—Magisterial Comments.

At the Bury County Police Court, before Messrs. G. Mills, A. T. Porritt, Councillor W. Scholes and Dr. Crawshaw, on Thursday, June 11th, Barzillari Stead, carter, East Ordsall-lane, Salford, was summoned for cruelty to a horse by working it in an unfit state at Whitefield, on the 13th May, and Samuel R. Teggin, carrier, Eccles New Road, Weaste, Manchester, was summoned for permitting the horse to be worked.

Mr. T. R. Bertwistle prosecuted on behalf of the R.S.P.C.A., and Mr. C. H. Pickstone defended.

Mr. Bertwistle opened. He said the facts were very simple so far as the proof of the cruelty was concerned, but there were a number of outside incidents it would be necessary for him to mention. It appeared that P.C. Tomlinson, who on that day was acting sergeant, saw Stead in charge of a horse attached to a cart passing through Whitefield. Noticing the animal was very lame he stopped the carter and pointed out the horse was lame. Stead said, "Yes, it is a bit lame, and it goes worse when it has been standing." Tomlinson noticed that the leg was covered with grease, and asked why it had been put on. Defendant said, "Well, its tendons are a bit off." They knew that was a Lancashire expression that there was something wrong. When asked how long the horse had been like that defendant replied, "I cannot say." P.C. Bowness was present and saw Tomlinson examine the horse. The animal, which was in very fair condition, was lame on the near fore leg, and when the horse stood he lifted the limb to rest it. Tomlinson told the carter the animal was not fit to be worked, that he must take it out of the cart and take it home, and the defendant did so. Witness went on to Besses, where he met P.C. Griffiths, who also saw the horse. The matter was reported to Inspector Faulkner, R.S.P.C.A., who went down the following day to the owner's place and examined the horse in company with P.C. Bowness.

P.C. Tomlinson stated that the horse was lame on the near fore leg, which was very tender and very much inflamed. Stead said the horse had gone worse since it was shod the previous Thursday. In witness's opinion the lameness was caused by the tendons binding on an old splint.

Cross examined: If the horse was badly shod it would cause lameness.

Inspector Faulkner stated that he examined the horse and found there was inflamed condition of the tendons of the leg. There was ringbone deposit immediately above the coronet, and the inflamed condition extended from the ringbone into the foot. The lameness, which was exceptionally acute, was due to the complication of the tendons and the ringbone deposit. The horse walked lame on the soft ground, and could scarcely put his foot down. Defendant said he had a veterinary surgeon who attended there regularly, but he would not give his name. Witness said he should be there the following morning, and defendant made no objections. The next day he went with Mr. Wren and found the horse locked up. Mrs. Teggin told them that her husband had left instructions that no one was to see the horse. Mr. Wren left his card, and asked Mrs. Teggin to tell her husband to write if he definitely refused to allow the horse to be examined. Mr. Wren received a post-card as follows:—"Mr. Wood has seen my horse again to-day, and says it will be fit for work in a day or two. Now he has had the shoe off and the foot poulticed. If you wish to know anything further refer to my vet."

In reply to Mr. Pickstone, witness said from defendant's attitude and from the fact that he had a veterinary surgeon, witness also wanted to have one.

Mr. Pickstone said the defendant could not be compelled to allow the Society's veterinary surgeon to examine the horse. The constable was the only person who had power in the matter.

The Clerk (Colonel Hall) said in some towns when a horse was stopped the man in charge was taken into custody.

Inspector Thomas, R.S.P.C.A., said when he saw Mr. Wood, the defendant's veterinary surgeon, Mr. Wood stated that he had seen the horse, and it was doing all right. It was a case where the nails had been driven too tight, and were binding on the sensitive part of the foot. The shoe had been taken off, the foot poulticed, and the horse would be all right in a day or two.

The question was again raised as to Mr. Wood refusing to allow another veterinary surgeon to see the horse, and

Colonel Hall said Mr. Wood's action did not prove or disprove the defendant's guilt. He thought too much importance was being attached to the point.

Inspector Thomas, continuing his evidence, said when he asked if he would allow another veterinary surgeon to see the horse he replied, "Certainly not." Mr. Wood then told him that it was the nails in the shoe that had caused the lameness.

Mr. A. B. Wren, veterinary surgeon, Bury, also gave evidence. In cross-examination he said if the horse was suffering from ringbone deposit it would still be there, and if the tendons were strained there would still be some symptoms. The treatment by Mr. Wood would remove the inflammation, and the horse would go all right for a time.

This concluded the case for the prosecution.

The defendant Stead said he had been employed by Teggin ten years, and had had charge of the horse about seven weeks before it was stopped. The horse was not lame when he took it out, but it went lame after dinner-time. The night before the horse got his leg over the halter-chain and "scarred" it. Witness rubbed some oil on the leg.

Ernest Edward Wood, M.R.C.V.S., Manchester, veterinary surgeon to the County Council and the Eccles Corporation, said when he saw the horse it was certainly very lame, and on the shoe being taken off he found that the cause was that three nails in the shoe were pressing on the sensitive structure of the foot. The shoe was taken off and matter was found in one of the nail holes. He could not find any ring bone or splint. It was by his instructions that Teggin refused to allow anyone to see the horse. He took the responsibility for that.

Cross-examined: The reason he refused to have another veterinary surgeon was because of something that happened in another case.

Mr. Bertwistle asked whether it would not have been better if witness had had his opinion backed up by another professional man.

Witness: As a rule veterinary surgeons don't back each other up like doctors. I can tell you that.

Col. Hall: Doctors don't always back each other up.

Mr. Pickstone: Neither do lawyers.

The Clerk pointed out that the action of the witness in refusing to allow another veterinary surgeon to see the horse might lead the magistrates to ignore the professional evidence and rely on the other. They could also adjourn the case and have an independent professional man to make an examination to see whether there was any ring bone or splint.

Wilkinson Guildhall, shoeing smith, said the horse was shod on the Friday before the Wednesday that it was stopped. Teggin stated he knew nothing of the lameness until after the horse was stopped.

Mr. Pickstone asked whether the magistrates intended to adjourn the case in order to have an independent examination made.

The magistrates deliberated in private for an hour and a half.

On returning into court the Clerk (Colonel Hall) announced that the case was adjourned for the horse to be examined by an independent veterinary surgeon to ascertain whether it was suffering from ring bone or splint or both, and if found to be so suffering then the court would deal with the case. The cost of this examination and also the cost of the prosecution vets. having an opportunity to examine the horse to be borne by the defendant. [The case was adjourned until Saturday].

On Saturday, June 13, Col. Hall, county magistrate's clerk at Bury, was called as a witness. He said that acting on the Magistrates' instructions, he met Mr. Dixon, veterinary surgeon, of Whitefield, on Friday morning. On arriving at defendant's place, witness told Teggin he was there on behalf of the justices to see the examination properly made. He handed to defendant and Mr. Dixon the following written instructions addressed to the latter:—"The justices require you to examine the near fore leg of this horse, and be in a position to say whether it is suffering from ringbone or splint or either of the two." The report stated:—

"I find there is splint on the inside of the shin bone on the near fore leg. About three inches from the top of the shin bone there is also ringbone. (Signed) J. Featherstone Dixon."

Mr. Dixon gave evidence, and said when at defendant's place he had the horse brought out. He wanted it moved on some stones, but Teggin said "Don't." He examined the horse and found both splint and ringbone.

Cross-examined: The horse walked lame. The lameness was due to the splint and ringbone. The horse had also sidebones very pronounced. As to the lameness, he could not differentiate between the splint and the ringbone, and the animal flinched on both. He had not seen the previous evidence. He had been kept absolutely in the dark. If the horse had been lamed through shoeing the lameness would not have continued a month. The horse was in pain. It flinched when the limb was touched, and gave way when walking. As to the splint, it could be seen. One could see immediately that the two legs were entirely different.

Mr. Pickstone submitted that in order to convict the Bench had to be satisfied that the employer personally knew that the horse was not in a fit state to be worked, and Mr. Teggin had stated that he had no previous knowledge.

The Bench retired to consider their decision. As Col. Hall had been a witness in the case, Mr. W. Smith acted as clerk. When the magistrates returned into court, Mr. George Mills (Chairman of the Bench) read their decision:—

"The Court finds this horse was on and prior to the 13th May suffering from lameness caused by a splint on the inside of the near fore leg and ringbone on the same limb, and that on the 13th May it was being worked by the defendant Stead and caused to be worked by the defendant Teggin in such a manner as by this lameness (of which each of the defendants was aware) to cause it unnecessary pain and suffering. The Court is of opinion the defendant and his veterinary surgeon deliberately placed obstacles in the way of the prosecution with the fixed purpose of hiding from or misleading the Court as to the facts, and in this regard it considers the veterinary surgeon acted most improperly, and badly advised his client.

With regard to the evidence of Veterinary Surgeon Wood, the court feels it cannot speak too strongly. Such evidence can only be explained in one of two ways:

- (a) that he is grossly incompetent;
- (b) that he was guilty of the greatest negligence in

his examination of the horse; which of these be the correct explanation witness is best able to judge.

The court is further strongly of opinion steps should be taken by the Council of the Royal College of Veterinary Surgeons towards inquiring into the circumstances of this case. It is to be regretted that it should be possible for evidence to be adduced of such a character as has been given in this case by Veterinary Surgeon Wood."

The court also said that they considered this an extremely bad case and imposed the following conditions: £10 as a fine and £18 costs on defendant Tegg, or in default of distress three months' imprisonment; 5s. as a fine and costs 12s. 6d. on defendant Stead, or in default of distress fourteen days' imprisonment. *Bury Guardian*

THANKS TO ELECTORS.

Dear Sir,

Permit me space thank most sincerely those gentlemen who recorded votes in my favour. Although insufficient to secure my return on this occasion, I hope in the future to be successful.—Yours very faithfully,

THEO. C. TOOPE.

Dover, June 15.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, June 16.

REGULAR FORCES. ARMY VETERINARY CORPS.

Lieut. A. Crapp to be Capt. Dated June 14.

Major A. W. Mason resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform. Dated June 17.

The following officers Army Veterinary Corps (T.F.) Welsh Division, have qualified for promotion to the rank of Captain at the recent examinations in B 2, 3, and 16:—

Lieut. R. D. Williams, Aberystwyth.

Lieut. H. L. Anthony, Tredegar.

Lieut. J. Campbell Hill, Llanelly.

Personal.

FOREMAN—MIDDLEHURST.—On June 10th, at Bayswater, Richard J. Foreman, M.R.C.V.S., son of the late William Foreman, M.D., of Wigan, Lancashire, to Cecelia, daughter of the late Henry Middlehurst, M.R.C.V.S., of Liverpool.

PAINE—BULL.—At the Presbyterian Church, East London, South Africa, on Saturday, May 16th, 1914, Florence Bull, of Bayswater, London, to Richard Paine, F.R.C.V.S., of Umtata, Tembuland.

OBITUARY

EDWARD JAMES MELLET, M.R.C.V.S., Henley-on-Thames. Graduated, Lond: Jan. 1882.

Mr. Mellett died on June 5th from acute croupous pneumonia. Aged 56.

WILLIAM MAYNARD, M.R.C.V.S., Romsey, Hants.

Lond: Dec., 1867.

Death occurred on Saturday, June 13, from syncope, following heart trouble, at the age of 70.

SPICER.—On the 13th June, at Crabwood, Oxted, Arnold Ralph, only son of Arnold and Flora Spicer, aged 10 years. The funeral took place on Tuesday, June 16, at Oxted.

CORRESPONDENCE.

[The following items were unavoidably held over last week, and several others are held over this week.]

THE ANNUAL "FIASCO."

Sir,

Ta! ta!—we're very much obliged to you, but we don't want to be bothered. Such, sir, is the blessing conferred on the gentlemen of the Council for the trouble they take in conducting the affairs of the profession, but as you justly remark, "it is a disgrace," and no alteration of date will "shake off the apathy." What a compliment to the Council! 22 members all told (including the 24 Councilmen!) Is not this a farce for a G.A.M.? I would suggest that any meeting which does not represent 5 per cent. of the whole of the profession should be adjourned *sine die*, for wherein is the use of 24 Councilmen agreeing to what they have done in the past year?—of course they agree. The fact is that a vast number of our profession are so selfish that they will not sacrifice a day's earnings even to pay their respects to those who work for them, on the one opportunity that offers itself. Where is the *esprit de corps*? Oh for a controversial fighting spirit of a Price, Dollar, M'Fadyean, or Hunting of 30 years ago! Opposition is good, not to stir up strife, but to bring forward beneficent ideas for the common weal. What a shameful mistake to take all and give nothing.—Yours faithfully,

H. D.

THE ANNUAL MEETING.

Sir,

In your leading article of last week you find fault with the members of the profession for not attending the annual meeting of the R.C.V.S. I beg to inform you that I attended the meeting and my name was put down in the book, but my name is not down in *The Veterinary Record*.—Yours truly,

GRAHAM REES-MOGG, Vet.-Capt.

Hyde Park Barracks, S.W.

June 9th.

[We regret that Capt. Rees-Mogg's name does not appear in the list of those present. Possibly he may have signed after our reporter had taken out the list.]

NASAL CATARRH.

Sir,

Permit me to ask the many readers of *The Veterinary Record* advice with respect to the treatment of the above complaint in a Pekingese. Nearly everything has been tried without success for 12 months. Perhaps some of our canine specialists would be able to suggest a suitable remedy, and its method of administration.—Yours faithfully,

"PEKIN."

June 10.

[Replies may be sent c/o *The Veterinary Record* if desired].

A DISPUTED ACCOUNT.

Sir,

In your issue of 6th inst., I notice you have coupled my name with the "Disputed account," which you report. I beg to say that I have nothing to do with that case, and if you will look up the reports in the daily papers you will find the plaintiff was Mr. Edward Sewell with whom I have no business connection.

Please see that this is corrected in your next number—with an apology.—Yours faithfully,

WILLIAM SEWELL, F.R.C.V.S.

51a Elizabeth St., Eaton Square, S.W.

June 16.

[We insert Mr. William Sewell's disclaimer with pleasure. The name as we printed it was given in the newspaper from which the report was taken, and was passed by our proof reader. The error was noticed, but unfortunately too late to make the correction].

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1355

JUNE 27, 1914.

VOL. XXVI.

BOARD OF AGRICULTURE—ANNUAL REPORT OF THE CHIEF VETERINARY OFFICER FOR THE YEAR 1913.

Two subjects call for special mention in that portion of the Board of Agriculture's report which deals with unscheduled disease, viz., swine erysipelas and epizootic abortion.

Swine erysipelas, for the first time, forms the subject of a special article. In 1913, records were kept of such outbreaks as came under the notice of the Board's veterinary officers, and thus we at last have some definite information as to the prevalence of the disease. These records, however, were collected solely from outbreaks which were believed or suspected to be swine fever, and it is quite certain that they are far from representing the total amount of disease in the kingdom. But even taken as they stand, they reveal a sufficiently serious state of affairs. They show that the disease exists in at least 59 administrative counties in Great Britain, and that its incidence includes such geographical extremes as Cardigan and Norfolk in one direction, and Cornwall and the Orkneys in another. In all, 1795 herds were found infected. In very many cases only one pig died, but so many of the herds were very small that this might be rather misleading. Again, the fact that all restrictions ceased directly the absence of swine fever was ascertained precludes any accurate mortality returns. But the mortality is certainly not a low one, and as the chief officer points out, the losses "are not to be reckoned by the death rate alone." Fat pigs—though by no means the only animals affected, as has been said—are the ones most frequently attacked, but even when they recover, the loss of condition is serious economically. Now and then, also, the disease assumes an exceptionally severe form in certain districts, as in the well-known Chatteris outbreak of 1905. And when we remember that many cases are recognisable by owners as not swine fever, and therefore are never reported, it is clear that the disease is now a very important one to us.

Restrictive measures are not likely to be of much use. The microbe lives as a saprophyte in the soil, hence "the affected pig is only one factor in the upkeep of the virus." Recognising this, the chief officer justly concludes that restrictions "would probably result in a maximum amount of incon-

venience to pig owners with the minimum amount of success." Instead of legislation, he advises preventive inoculation, which the Board has already been recommending to owners for some time. Two methods are applicable—one by an anti-serum, the other by a combination of anti-serum and pure bacillary culture. The first very speedily confers an immunity which only lasts for about ten days, and this method should be used when the disease has actually appeared in a herd.

The second method immunises for probably from six months to a year; and this should supplement the more transient first method. Of course, ordinary sanitary measures—especially with regard to the flooring—are also of importance. The chief officer hopes to be able to supply serum and vaccines, and evidently trusts them to control the disease.

With epizootic abortion, the outlook is beginning to be hopeful. A reliable diagnostic blood-test, which may, perhaps, become available to the practitioner but at present is only applicable in the laboratory, is now in the Board's hands. The results, so far, of artificial immunisation before pregnancy are described as "certainly very encouraging," but as each observation requires about nine months for its completion, the data available as yet are hardly sufficient to warrant a definite conclusion. It is hoped to present a statement within the next four months. Meanwhile, the Board has been considering the possibilities of legislation. Two methods have been proposed in conjunction with compulsory reporting. The first is to restrict the movement of recently aborted animals and those suspected of being infected; the second, to restrict only those which have aborted. A modification of the second method is now on trial in Devonshire, but for too short a time to assess the results. Obviously the first plan is far preferable; and, now that the discovery of a reliable diagnostic test has removed the fear of detaining uninfected cows for long periods on suspicion, the time seems ripe for its adoption. The Chief Officer, however, prefers to wait till the value of preventive inoculation is definitely known before taking action. Preventive inoculation may obviate the necessity of legislation; if not, there is little doubt that legislation is near.

Enzootic ovine abortion is also touched upon—the recent discoveries regarding it, which we reviewed in this column not long ago, are briefly summarised.

Altogether the report (Cd. 7423), which can be obtained from Messrs. Wyman and Sons, Fetter Lane, E.C., for 2½d., is well worth study by every country practitioner.

TREATMENT OF FOALS—MORPHIA.

Mr. Jolliffe in his article on the death of his foal, has raised some very interesting questions of general interest, and since he asks for remarks on the case, I think his queries may be answered, according to my experience, in the following way:

1. The foal was probably to some extent killed by kindness.

2. A foal should not be forcibly fed during its first 24 hours. I should not worry too much about a foal not sucking for even two days, and in many cases the stomach of the newly-born is better without food. Forcible feeding so far as actual "drenching" is concerned is never advisable.

A foal may, however, very often be induced to suck sugared, warm milk out of a bottle provided

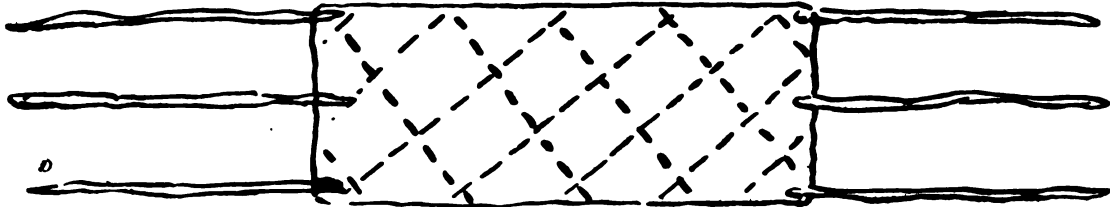

of being a dry application. With two bags, one on the animal, and one in the oven, hot applications may be continued indefinitely. The salt is best retained in its place by the bag being sewn across in diagonals.

This method I practised and recommended in *The Veterinary Journal* twenty years ago.

It frequently happens in treating foals that a stimulant is found to be necessary.

Unless absolutely indicated, I believe stimulants are better not given. When necessary, I have found the one most effective, best tolerated and most liked by foals is port wine mixed with an equal quantity of warm water, with sugar. This mixture is often greedily sucked out of the bottle, after a first acquaintance with it.

H. C. WILKIE, F.R.C.V.S., F.Z.S.

with some sort of teat (to prevent too great a flow) when it altogether declines to suck the mare.

This is, I think, in nearly all cases due to an acid condition of the mare's milk after the disappearance of the colostrum, and this condition I have found may be remedied by giving the mare one or two doses of bicarbonate of soda in ounce doses, and milking her well out at least five or six times a day.

3. I have found refusal to suck not uncommon in foals, newly born, and nearly always due to the state of the mare.

4. I believe "drenching" is a very undesirable procedure in newly born foals, and when efforts are made to induce a foal to suck out of a bottle, the milk should be prevented from running freely and the head should never be pushed high.

5. The condition of the mare mentioned and the loss of colostrum seems to account for the intestinal derangement of the foal.

I doubt, however, if the loss of colostrum in itself is of the importance frequently attributed to it. The flush of milk and its temporarily abnormal state probably account more directly for its indigestibility.

6. Cows milk undiluted and somewhat rich in butter fat usually acts as a laxative in newly-born foals. A very undesirable one, however, as it is not well tolerated.

7. It is doubtful if half a grain of morphia would kill a strong foal, but might be the "last straw" for a weak one. I believe morphia in any effective doses at all is injurious to the newly born. Abdominal pain in such animals is best controlled by warm rectal injections, massage and the external application of heat.

I think hot fomentations are undesirable. Salt retains heat very well, and has the great advantage

BRAIN TUMOURS IN TWO MARES.

(CHOLESTEATOMATA VASCULOSA).

By JOHN LINDSAY, M.D., Glasgow Veterinary College.

The first of these two cases occurred in the practice of Mr. Duncan McFarlane, M.R.C.V.S., Doune, and Mr. Harold McD. Paul, his assistant, sent the specimen to the Glasgow Veterinary College for examination, along with the following clinical notes.

About the end of November, 1911, we were called to examine a 14 years old Clydesdale mare in a horse-box at Doune Station. We found her down and unable to rise. Temp. 102, pulse 50, weak and thin, mucous membranes practically normal, eye dull and sleepy looking.

Diagnosis. Probably a slight injury to the back from falling in the horse-box.

Treatment. Stimulating liniment to back, and stimulant draught given, mare rugged and left in the box for the night.

Next morning she was able to walk to our infirmary, a distance of 200 yards, and on the following morning she was delivered to her owner, and walked three miles home.

We heard no more about her until three weeks later, when we were asked to treat her for colic. Mr. McFarlane attended and found her badly pained, temperature 103, pulse 60, mucous membranes injected, respirations laboured, mare very restless, boring her head into the corner of the box, staggering when made to move, and apparently in great agony.

Diagnosis. Probably pressure on the brain due to a tumour.

Treatment. 3vii. ball given, and chloral 3j. Twelve nux vomica and ammon. carb. balls were sent, one to be given twice daily.

The mare fed well for a time but showed little signs of recovery; as, however, the owner was anxious to get another foal off her we still continued treatment. She was blistered over the poll and sacrum with ol. canthar., and kept on tonic balls one week and stimulant balls another, and under this treatment she seemed to improve a little. In February she went off her food, and as her teeth were not of the best we dressed them, but without beneficial result. She seemed incapable of prehension at this time, but if a bunch of hay was placed between her molars she would chew it, and then appear to go to sleep without swallowing it.

From this time until her death on 3rd March she was unable to go out of her box, and moved only after considerable persuasion. If backed she sat down. She could drink pretty well, and even made attempts at eating soft mash, but very little hay was partaken of. Although receiving six bottles of gruel per day she became very much emaciated, the muscles most wasted being those of the back and quarters. Emaciation, listlessness, drowsiness and staggering became more and more pronounced. Her boring turns appeared oftener and lasted longer—from 12 to 24 hours—and it was worthy of note that when boring she always carried a high head. Urination was most irregular, but the passage of the catheter had never to be resorted to. The temperature varied between 102 and 103, the pulse between 50 and 55. The mucous membranes were injected only when she was pained. Only at these times also was the respiration abnormal, being then laboured and the nostrils dilated.

She died, as already stated, on 3rd March, and on the following day a post mortem examination was made at the owner's request. The bowels and stomach appeared to be normal. The kidneys and liver appeared to be harder than normal, but were not cirrhotic. The spleen was normal. The heart valves were slightly thickened. The bladder was very much distended and dilated and contained two quarts of highly coloured urine. Great difficulty was experienced in removing the brain on account of its softness, and for that reason also the cerebellum could not be preserved. The cord appeared soft, and the spinal canal contained a reddish coloured fluid of the consistence of serum. Both eyes showed signs of approaching blindness.

The late Mr. David Constable, Inchtute, who had had the mare under observation at an earlier date, was communicated with and reported that "he had attended her at least six times, and came to the conclusion that there was pressure on the brain, possibly from a tumour. She presented a comatose condition, partial blindness, staggering gait, and occasionally colicky pains which continued for fully two days. Latterly the attacks were more frequent and more severe."

Pathological Report by Dr. Lindsay:—The specimen consisted of the cerebrum and mid-brain. It was soft and somewhat torn. In the longitudinal fissure lay unattached a tumour (A). From

subsequent investigation it appeared that this had originated in the left lateral ventricle. The rupture of the corpus callosum which permitted its escape probably occurred from handling after death and not during life. The tumour was ovoid in shape measuring $7 \times 4 \times 2.5$ centimetres, and it weighed 53 grammes. In consistence it was firm, almost hard. Externally it was dark bluish grey in colour. On section the cut surface was brownish with whitish granules, and showed numerous sparkling points when held obliquely to the light. When filter paper was pressed on the cut surface it became coated with similar shining points. These were adherent crystals of cholesterol.

In the right lateral ventricle another tumour (B) was found of the same shape, colour, consistence, and texture as (A) but rather smaller, its weight being 36 grammes. It lay in the body of the ventricle, not extending into the anterior or posterior cornua, and it was fixed only by exudate. On one side was the torn end of a small blood vessel about 1 mm. in diameter.

The surface of the cerebral hemispheres showed no evidence of compression, but the cavities of the lateral ventricles, except the cornua, were distended and shaped to the form of the tumours.

Microscopically, sections showed an external boundary zone or capsule of mature fibrous connective tissue, at places on the surface of which were deposits of fibrinous exudate. The interior was composed of a network of interlacing bundles of connective tissue fibres, intermingled with which were numerous trabeculae of homogeneous fibrinoid material. Everywhere the tissue was permeated with small round cells, and on the surface of the fibrous strands next the interspaces were many cells which were either irregularly disposed endothelial cells or young fibroblasts. There were few formed blood vessels, but many of the interspaces of the network were occupied by altered blood corpuscles and fibrin. Embedded everywhere in the tissue were clusters of granular masses of pigment, variable in size, and ranging in tint from pale yellow to dark brown. Cholesterol, extracted by ether, amounted approximately to 20 per cent. by weight of the dried tumour substance. There was no calcification.

A second case occurred in the practice of Mr. James Macfarlane, M.R.C.V.S., West Nile Street, Glasgow, who also sent the specimen to the Glasgow Veterinary College, and supplied the following clinical data.

The subject was an Irish-bred mare, aged nine years. First signs of illness, taking the form of a disinclination to go forward, appeared three weeks before the final development. On this later occasion the mare was out at her work when she refused to go, and lay down. A float was sent for and every means was tried to get her to enter it, but she refused, and it was decided to walk her home. This was done, she following the float. A dose of physic was given and she was allowed to stand in the stable for three days. Thereafter she was sent out to work again and did well for a few days. Kept in one morning, as she was not feeding well,

she later in the same day became very dull and disinclined to move.

When examined by the veterinary surgeon she was found standing with her head inclined to the right and boring forward against the wall. On being asked to go forward she did so with a bound. In this condition she remained until the following day, and while being removed from the stall to a loose box she fell. The mare was now completely blind, and seemed to bore more than ever. Gradually getting worse she was destroyed on the following morning.

The mare came into the service of the firm, Messrs. Wordie and Co., only two months before the appearance of the first symptoms of illness. All the owners, in whose possession she was known to have been previously, were written to, and replied that they never knew her to have a day's illness during the time they had her.

The treatment followed consisted of the administration of large doses of sedatives along with full doses of Pot. iodide and iodine.

Pathological report by Dr. Lindsay. When received by me the brain had been sliced and the tumour lay free. It was rounded in form, softer than those in the first case, and smaller. It weighed 14.6 grammes. Microscopically the texture was somewhat open, there being a framework of homogeneous, or faintly fibrillated tissue, with spindle shaped cells embedded in it, mainly, if not entirely, mature fibrous connective tissue. Enclosed between or overlying the strands of this were cells, single or in masses, many of which, although varying in form, agreed in having much cytoplasm and large nuclei with delicate chromatin network, fibroblasts. Many others were small in size with very dark nuclei, or larger with deeply staining lobulated or fragmented nuclei, leucocytoid or plasma cells. Some of the interspaces between the trabeculae were incompletely lined by cells which appeared to be proliferated endothelium; and solid masses of such cells were frequent. There were many thick-walled vessels, most of which showed hyaline degeneration of the walls, the proliferated endothelium being surrounded by a homogeneous zone containing few or no nuclei. Scattered through the tumour were numerous granular masses of irregular size and shape, probably altered blood pigment. A few large, torn blood vessels hung from a part of the external surface. Cholesterolin, amounting to about 20 per cent. by weight of the dried tissue was extracted by ether.

The tumours in both cases are local overgrowths of the choroid plexus, and are classified as *cholesteatomata vasculosa*.

At the meeting of the Council of the Hunters' Improvement Society on June 11, it was unanimously resolved to nominate a delegate to represent the Society at the International Veterinary Congress, and the Secretary was instructed to write to the President, Sir Merrik Burrell, Bart., and ask him to represent them.

GOVERNMENT PUBLICATIONS.—Messrs. Wyman and Sons, Ltd., have published the following post free:—Bill: Vivisection Abolition, price 1½d.

ABSTRACTS FROM FOREIGN JOURNALS

NARCOSIS BY CHLORAL HYDRATE IN HORSES.

Früs, a veterinary surgeon in Copenhagen, has published (*Maanedskrift for Dyrtaeger*) an article upon this subject. In chloral hydrate, he says, veterinary medicine possesses a narcotic with incontestable advantages over chloroform, ether, and morphia; and it is surprising that it is not more used by veterinary surgeons.

All methods of using chlorol, however, have their disadvantages.

Eberlein, who introduced its use by the stomach, showed that this method produces an admirable total narcosis, and that chloral hydrate is very adaptable for use as a total narcotic in veterinary surgery, and in most cases suffices for the purpose alone, without any other drugs.

One question which is very important in the stomachal administration of chloral is the disinclination of horses to take the drug dissolved in their drinking water. The author has investigated this point in Prof. Eberlein's clinique in Berlin, and has collected records of 685 horses of very different breeds and ages. The ages varied from foals of seven months to horses of twenty years.

A so-called "time of preparation" preceded the administration of chloral per os. This period lasted 24 hours in summer and 48 hours in winter. During it the horses received only half rations; and on the day of operation they received nothing, *especially* no drinking water.

The chloral must be *freshly dissolved* in a little water, and is then given to the horse in half a bucket of water.

The dose varies (in accordance with the breed, size of the horse, duration of the operation, and time of the year) from 20 to 70 grammes (=roughly from 5 drachms to nearly 2½ oz.), and averages 40 grammes (=about 1½ oz.)

If the horse dislikes the draught, various courses may be adopted. Often the horse only drinks when he is standing in his accustomed place. Many horses take the chloral better if some bran or sugar is added to the drinking water. If the horse absolutely refuses to take the chloral, it may be administered by the drenching bottle or given in the form of a ball.

If it is desired to shorten the period of preparation, small doses of salines may be given.

The author's records show that, of the 685 horses, 503 (=73.4 per cent.) took the chloral without difficulty, and 105 horses (=15.3 per cent.) took it after bran had been added. Therefore altogether 608 horses (=88.8 per cent.) took the chloral in the drinking water.

In 74 cases the chloral was given as a ball, and in two cases as an electuary. One horse took almost the whole dose in the drinking water and then received a small chloral clyster. Of 74 horses which would not take the chloral in the drinking water, 22 were not prepared, 7 had been deprived

of water for 12 hours, 1 for 20 hours, 30 for 24 hours, 7 for 48 hours, and 7 for 72 hours.

Deducting the 22 unprepared horses, the number of those to which the chloral had to be given as a ball remains 52, thus equalling only 7.6 per cent. of the 685 horses.

In general, well-bred horses refused chloral longer than heavy and coarser ones. Within the same breed, however, individual peculiarities were manifest.

Often the method is successful even after imperfect preparation. But as a general rule the horse should be deprived of water at least 24 hours before offering the chloral.—*Berliner Tier. Woch.*

W. R. C.

CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A. SOUTHERN BRANCH.]

The usual monthly meeting was held at 10 Red Lion Square, W.C., on Thursday, June 4th. Prof. G. H. Wooldridge, President, in the chair. The following Fellows signed the attendance book: Messrs. J. Rowe, J. B. Buxton, G. Gordon, B. Gorton, R. Bennett, N. Almond, G. H. Livesey, H. D. Jones, R. Eaglesham, E. L. Stroud, W. N. Thompson, W. D. Halfhead, T. S. Price, Capt. G. Rees-Mogg, G. D. Martin, M. Cahill, W. R. Clarke, W. Perryman, W. Willis, F. J. Taylor, S. H. Slocock, S. L. Slocock, and Hugh A. MacCormack, Hon. Sec.

On the motion of Mr. E. L. Stroud, seconded by Mr. T. S. Price, the minutes of the last meeting were taken as read, and signed.

CORRESPONDENCE.

The Hon. Sec. reported the receipt of letters and telegrams from Messrs. W. Shipley, J. C. Coleman, J. W. McIntosh, and W. S. Mulvey regretting inability to attend.

He had received two circulars from Mr. Toope, relating to the scale of fees which should be adopted by the National Veterinary Medical Association. Also, that Major Holmes, D.Sc., had forwarded two memoirs of the Department of Agriculture in India, relating to (1) Curative treatment of hæmorrhagic septicæmia by administration of iodine, and other notes on chemotherapy in rinderpest and hæmorrhagic septicæmia; (2) Vitality of hæmorrhagic septicæmia organisms outside the body.

On the motion of Mr. T. S. Price, seconded by Mr. N. Almond, consideration of the subject matter of Mr. Toope's communications was deferred until the next meeting, in order that copies might be obtained and sent to Fellows.

On the motion of Capt. G. Rees-Mogg, seconded by Mr. T. S. Price, resolved that the thanks of the Society be conveyed to Major Holmes for his communication.

MORBID SPECIMENS.

Mr. S. L. SLOCOCK introduced a specimen illustrating a fracture of the basi-occiput of a pony. The pony was in a field with some horses, and when seen at 4.30 p.m. was all right. The speaker saw the animal at 8.30 p.m. of the same day, and it was then suffering from complete paralysis. The holes seen in the specimens somewhat suggested that made by a spent or ricocheted bullet. There was no history in the case. No one had seen what had happened, there were no rifle ranges in the neighbourhood, and no bullet was found.

The President, in submitting a specimen, remarked that in the absence of Mr. McIntosh he could not give

details of history. This case was that of a pet kitten, young half-Persian, three or four months old. Lately the kitten became listless and grew thin, but had been taking food fairly well until about Friday or Saturday last, when it began to "blow" and breathe hurriedly. Mr. McIntosh sent it to the speaker, who found it even more advanced in its illness than Mr. McIntosh had supposed; it was very thin and weak. He was able to feel certain enlarged lymphatic glands in the abdomen, and from the position of the lymphatics and their nature, he gathered it was a case of lymphadenitis probably of tubercular origin. At the speaker's suggestion Mr. McIntosh permitted the kitten to be destroyed by chloroform when the condition was found to be more extended than had been supposed. Both lungs were nearly solid. There were none of the symptoms of the moist cough as might have been expected in such cases. The mesenteric lymphatics were very considerably enlarged, especially in the angle formed at the junction of the ileum with the cæcum. There was not the usual characteristic caseation of tuberculous lymphatics, because the cat was too young for their formation. The bronchial lymphatics were also enlarged. The spleen was simply a mass of "hob-nail" lumps, the lungs were quite solid, the lymphatic glands in the mediastinum very enlarged. The spleen left no room for doubt, but micro-organisms were not numerous. It was unusual to find the disease so extensive in so young an animal. In older cats, cavities in the lungs were more frequent, and therefore there would be more coughing and more danger of spreading. In this case he regarded the lung lesion as secondary to the abdominal, on account of the general diffuse affection of both lungs.

Mr. G. H. LIVESEY observed that Professor Wooldridge's specimen was extremely interesting as showing how consumption in a cat might be developed in a very young animal. He thought there was a tendency to ignore the fact that consumption was so frequent, not only in the cat but in the dog. Of the two varieties of cat there was more consumption among the long-haired Persian than among the short-haired cats. Possibly the longer hair increased the liability to pick up dust, the cat infecting its alimentary canal from its fur, creating hair balls, etc., in its inside, which, in their passage through the intestine, were more likely to infect the mesenteric glands. To the speaker the most interesting symptom about the case submitted was the absence of coughing; the frequent absence of coughing was an interesting feature in all cases of consumption among cats or dogs when compared with similar stages of the disease in the human being, in whom consumption was usually associated with rather a short cough, particularly in the morning. Animals went through the malady without showing the persistent hacking cough occurring with human beings. In post-mortems he had found that animals emaciated and in poor condition, although they had not been condemned for any specific disease, were frequently riddled with consumption, yet they had never been noticed to cough in their lifetime.

Looking at the condition of the lungs and the organs generally in the specimen submitted, it was astonishing to think that an animal in that condition had never had a suffocating choking cough. From the colour of the lungs it could be seen that the circulation was almost wholly impeded. He had seen dogs riddled with consumption, but in one case he had in mind only once in three months illness was the dog heard to cough. He could not explain it. Whether coughing was more readily performed in human beings he could not say, he should not think so, as the coughing reflex was highly developed in cats and dogs. How the lungs of these small animals could be so intensely invaded by foreign organisms without being accompanied by the reflex act

of coughing and expectoration, required further explanation.

Mr. DUNLOP MARTIN called attention to a very severe case of tuberculosis in a cat. He had sent the viscera to Prof. Wooldridge for examination, because they showed such extensive characteristic lesions. The condition most interesting to the speaker was the large amount of pleuritic effusion of a very peculiar greenish soupy colour; the cat was a small-sized adult, but in the two sides of the thorax there must have been the better part of a pint of fluid. There was no history of coughing, as in Mr. Livesey's case. The cat had been in his care before for a few days while the owners were away three months, and had suffered considerably from diarrhoea, which, however, yielded to ordinary treatment, and the cat was practically normal on its return home. Recently he was called to see the animal, and upon examination advised destruction, and this was carried out.

The PRESIDENT stated that in the case mentioned by Mr. Martin he had found tubercle bacilli in large numbers, there had been no difficulty in demonstrating that. It was remarkable that here, again, there was no cough, more so in this case than in the one he had submitted. It was probable that in this instance there was a discharge of tubercle bacilli from the nose. Though unlikely in Mr. Martin's case, in the speaker's case it was probable that the lesions were mainly in the interstitial tissue and were conveyed thither by the blood stream. In Mr. Martin's case there was most likely local affection (broncho-pneumonia) in the first instance, which was more likely to prove dangerous. It was difficult to over-estimate the danger to children, particularly from furry kittens, which were cuddled and petted. Enquiry was sometimes made as to the type of organism, whether bovine or human. Both types were undoubtedly met with, whether in the abdominal or pulmonary form. It was impossible to tell by microscopic examination alone; biological examination, inoculation, and experiment were needed. Some cats took infection from human beings living in tuberculous households, others from the milk of tuberculous cows.

Mr. DUNLOP MARTIN referred to a case of metritis in a fox terrier bitch, the viscera having been sent to Prof. Wooldridge. The bitch was just a year old. Nothing had been noticed by the owner until the period of oestrus, which began about a month before the speaker had seen the bitch, when she was practically *in extremis*, and there was a profuse bloody discharge. She was very weak and exhausted, very anæmic, and he could only advise her destruction. She was the youngest bitch he had ever heard of in such a condition. The uterus was enormously enlarged, the enlargement beginning about $\frac{1}{2}$ in. to $\frac{3}{4}$ in. from the cervix and extending practically the whole length of the body of the uterus and some distance beyond the division into the cornua.

The PRESIDENT remarked that this case was one of chronic metritis, met with frequently in bitches seven or eight years old, and in many cases those that had not had puppies. It was extraordinary to find it in so young a bitch. There might have been some constriction of the *os uteri*, preventing conception, and infection from some other source may have occurred, preventing the escape of the discharge. It was not possible to say definitely. If diagnosed sufficiently early, before the bitch was in a state of collapse, the only treatment he could suggest was hysterotomy. In many of such cases an organism was present which corresponded with, and he believed was, the *bacillus coli*, and for such affections vaccination might be effective. He had had cases in which he had applied this treatment with beneficial results; others in which no benefit was derived from it. In cases of valuable bitches where the owners did not desire the performance of a radical operation, it

might be worth while to vaccinate first, but if that should prove of no avail then resort to the more drastic treatment of extirpation of the uterus.

SOME CLINICAL CASES.—By R. EAGLESHAM.

DISCUSSION.

(Continued from p. 758.)

The PRESIDENT expressed regret at the absence of Prof. Macqueen who, in the ordinary course, was to have resumed the discussion on these cases.

Mr. W. PERRYMAN said he had read the paper in *The Record* with some astonishment. He had always been sceptical about rheumatism in horses, a subject which he thought was spoken of much as influenza in the human subject and distemper in the dog, and he might add, as influenza in the cat, the term often indicated a "cloudy" diagnosis. From motives of conscientiousness—to which he did not lay sole claim—he had never been satisfied that the horse was frequently attacked with rheumatism. Mr. Eaglesham had described one or two cases rather minutely. Possibly the cases described were those in which young animals had been over-worked or some other cause had operated which Mr. Eaglesham had not found out and they therefore had regarded them as rheumatism. The animal in question had shown thickening of the sheaths of the tendon in the sesamoid region, and of the check ligament. When large numbers of horses were imported, particularly from Canada, it was a common experience with practitioners that the young horses, when brought to London, would, if they were not carefully worked or "seasoned," show after a short period the general stiffness to which Mr. Eaglesham had referred. These horses had a great tendency to lie down. At the present time he had an animal that was always lying down and would not eat its food when up. In these cases he generally paid regard to the check ligament, and frequently found heat and tenderness, and after a short time thickening. Unless the animal were at once rested the train of symptoms mentioned by Mr. Eaglesham would follow. There was thickening and inability to walk, especially on first rising, the horse would get up but could not get his heels down properly. As time went on there was contraction of the tendons, knuckling over the fetlocks, and ultimately ruination of the animal. If that were rheumatism he feared he had wrongly diagnosed many of his cases. He had always associated the trouble as a characteristic of young animals, particularly the hot-headed ones, also as showing the breakdown of the fibrous tissues of the tendons, followed by infiltration of interstitial tissue, and all the sequelæ of contraction. He quite agreed that many young animals fell lame and showed that particular train of symptoms after sickness, but he had always regarded it as a consequence of inability to do the work required of them. The trouble occurred less in some stables than in others—more so where the masters were inconsiderate of the animals. It was a good thing that some young animals did fall sick on going into the stables, because masters often did not pay the attention to training and conditioning that they should; sickness created alarm, which resulted in the animals receiving better treatment in respect to work. The only cases of rheumatism which the speaker had seen were those in which the peculiar cracking of the joints was heard as the animal walked round. His own experience and Mr. Eaglesham's paper enabled him to gather that it was nearly always the young horse that was affected by the symptoms mentioned in the paper; it was more natural to look for rheumatism in old horses.

In conclusion, he was a doubtful believer in rheumatism, even chronic or acute rheumatism, and he believed that many so-called cases were capable of other explanations. If, in many cases, the animals had been better

conditioned, he did not think that the running over of the fetlock joints and general contraction would be so frequent.

Mr. H. D. JONES was specially interested in rheumatic tendonitis. He asked what interval of time elapsed between the convalescent stage of the illness and the time the horse was first put to work. He had had many of these cases, and could not agree with Mr. Perryman's observations about overwork, as many of the animals he was referring to had done no work at all. The horses had been admitted to the infirmary and had been very ill, mostly with pleurisy and effusion into the chest. After about a fortnight of convalescence, the legs of the animals had been found, on manipulation, to be very tender in the region of sesamoid sheath. The slightest touch caused the animal to lift the leg very high. Next day the same animal would be lame in the hind leg, and he had seen an animal lame in three different legs in twenty-four hours. Whether the lameness was rheumatic or not he could not say, but it was certainly metastatic, and of an acute order. The animals did not show the same degree of pain when the hind legs were affected as in the case of the front leg.

A very interesting article, by Major Martin, had appeared in *The Record* of January 25th, 1913, in which he had pointed out that nearly every case of metastatic lameness which he had, occurred after pleurisy with effusion into the chest; he had added that recovery from pleuritic effusion was, in nine cases, interrupted by painful swelling of the sesamoid sheath at the back of the fetlock. In four cases the trouble had occurred in the fore legs, and in one in the hind leg, and was accompanied by hot joint, general rise of temperature and constitutional disturbance. He would ask Mr. Eaglesham whether he had noticed that metastatic lameness followed tapping and drawing of blood in the early stages of pleurisy. The speaker had lately tapped a considerable number of horses for pleurisy and pneumonia—not easily differentiated in the early stages—and thought he had found a diminution in the complaint of metastatic lameness. He had never seen any beneficial results from treatment in the acute stages. He had tried bandaging and the ordinary treatment for rheumatism, but had secured no benefit. He had had animals lame for six months with the complaint. A slight benefit had followed puncture with the thermal cautery with antiseptic precautions, in the chronic stage, when there was fibrous thickening in the sesamoid sheath.

Mr. PRICE: I have been very interested in the discussion we have had to-night, especially when I remember I was at the Veterinary College in the days of Spooner. He taught us even in those days that navicular disease, was often the cause of thickened tendons, and he was sure the disease was of a rheumatic type, he recognised how shifty the disease was. When you trotted the horse up one day the lameness would be on one leg, the next day on both, and a few days after would change again: proving beyond doubt it was of a rheumatic type, and when unnerved the horse would often go sound, even if the tendons were thickened. I have preached the same doctrine to my clients ever since, and should recommend you all to stick to the opinion that the disease in question is of a rheumatic type, it is well to have a definite opinion of cases of this kind.

I am well aware you can have sprained and thickened tendons without navicular disease, but in my opinion, which is backed up with 40 years experience, I can safely say that seven thickened flexor fore tendons out of ten are due primarily to navicular disease: and these cases can be relieved and made to go sound by dividing the nerves. How often do we find chronic cases of thick tendons which have been blistered, fired, blistered again and turned out into straw-fed or grass for months, and come up little or no better. But when the median and

outside plantar have been divided—which Prof. Hobday is so keen on—the horse goes sound, and if put into the right job, will do a lot of work.

I don't know any disease you can waste more time and money than you can by firing and blistering cases of this description. It is best, as Spooner said in the olden times, "Don't be in a hurry: make sure of your diagnosis, as it will save you a lot of trouble and bring you into repute." I don't think science has made much advance with these diseases since the days of Spooner. I thank the essayist for his paper.

Mr. S. H. SLOCOCK apologised to Mr. Eaglesham for not having read his article in the journal. Associated, as he had been, with lame horses for a good many years, he began to think, like Mr. Perryman, that his diagnosis had been wrong, especially as he disagreed with both Mr. Perryman and Mr. Price. He was a great believer in the actual existence of rheumatism in the cases referred to; he could not associate contraction of the tendon with anything but rheumatism. He had had horses which came in sick, perhaps after a day's work, and just about at the time when they were recovering and they seemed fit for work again, acute metastatic lameness occurred with thickening of the various tendonal structures. If that were not rheumatism what was it? Mr. Price's suggestion that navicular disease was rheumatic in nature had never occurred to the speaker. It had, however, occurred to him that laminitis was rheumatic in origin, especially sub-acute laminitis. He disagreed with Mr. Perryman as to the check ligament. He had never associated a sprain of the check ligament with rheumatism. He had been taught that lameness in the horse started with the check ligament, but he was not many years in practice before thinking otherwise. He thought now, however, that sprain of the check ligament, while causing lameness, was secondary to ringbone. He therefore regarded lameness as arising from ringbone formation, more particularly at the back of the pastern bones, just in the flexure. A deposit in that position was bound to make a horse knuckle up his fetlock, just as an injury to the frog would do, with a resulting undue strain on the check ligament. He was unaware of any particular treatment for rheumatism except turning a horse out to grass; that, however, did not recommend itself to the veterinary surgeon. If put to grass the animals frequently came round again. Much of the benefit he attributed to change of diet, and still more to the continued slow exercise, the horse not being allowed to stand still for hours at a stretch as in the stable.

Capt. G. REES-MOGG remarked in connection with rheumatic affections, that he had often had lame horses, but had frequently been defeated in his efforts to find where they were lame. The horse might improve after rest with cold water applications, etc., but go lame again after work. He had had experience of a dozen of such cases. The affection might, or might not be rheumatic, or it might indirectly be due to rheumatism. In at least a dozen post-mortems he had found tiny lumps, about the size of a pea, on the back of the os coronæ. If there were some rheumatic disease of the tendon, which played on the bones it might possibly have something to do with the lameness, or it might be entirely due to osteitis of the os coronæ.

Mr. DUNLOP MARTIN referred to Mr. Slocock's remarks on the strain of the check ligament, observing that in his experience this strain was associated with some over extension—undue dropping and over extension of the tendons, which called into play the action of the check ligament. He had never regarded this strain as excited in the manner indicated by Mr. Slocock.

Mr. W. N. THOMPSON mentioned the case of subcutaneous sarcomata which he had brought forward at the previous meeting. Since then he had been able to procure a photograph and to look up the case. He

desired to make one or two corrections. The horse had been under his observation for four years, not six or seven years. He had said that Sir John M'Fadyean had examined a section of the growth, and had classified it as sarcoma; to that he would add that Sir John was very definite in stating that the internal organs were all healthy.

Mr. J. B. BUXTON referred to the lameness of a cart horse which came on and went off with weather changes; that might be a coincidence, but if the lameness were not due to rheumatism he had not the faintest idea of the cause.

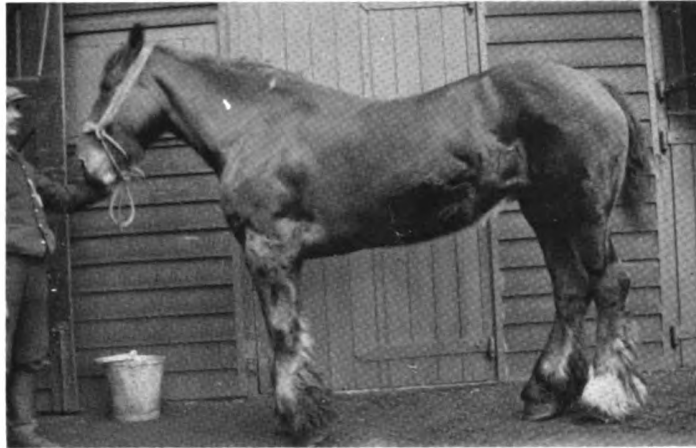

The PRESIDENT thanked Mr. Eaglesham for bringing forward his most interesting cases, and remarked that the discussion had that evening turned mainly on one of the three sets of cases, namely, rheumatic tendonitis, but the others, although not so debatable were equally interesting. The case of multiple subcutaneous sarcomata, for instance, was a very rare one, and Mr. Thompson's case was interesting also. He had seen Mr. Thompson's case at the time that it came in, and only on the day of the meeting the speaker had made unsuccessful efforts to get a photograph; he was glad therefore that Mr. Thompson had been able to do so. He had seen the post-mortem and could confirm Mr. Thompson's statement that there were no internal growths, such as might have been expected. The lumps described by Mr. Eaglesham and Mr. Thompson were perfectly free from pain and were quite cold, and, apparently, did not cause inconvenience except where they got in the way of harness. It was remarkable that an animal should be so extensively affected by growths of that kind without showing any general systemic affection. It was well to hear of such cases occasionally, as sometimes there were difficulties relative to diagnosis; the whole course of development was not seen, and when animals were brought in without any history, the veterinary surgeon might be misled into diagnosing botryomycosis or farcy buds, although the fact that the growths come on gradually discounted that.

With regard to renal disease and calculi in the horse, that was of considerable interest. He had not had a case under observation so long as Mr. Eaglesham had, but he was interested in the statement that there was no evidence of colic during the course of the disease such as might have been attributed to the kidney. He held the view that some cases of recurrent colic were due to renal calculi. In post-mortems on horses that had died from other causes he had sometimes met with calculi as big as two fists put together affecting one kidney, obliterating the whole of the kidney substances, the other kidney working quite normally. It was hardly conceivable that calculi had reached that size without causing abdominal pains that had been diagnosed, possibly, as colic. That form of multiple small calculi or sabulous matter was more common, he had found, in cows than in horses, and was often associated with cystitis. He believed that Mr. Eaglesham found the offensively smelling urine almost always associated with cystitis.

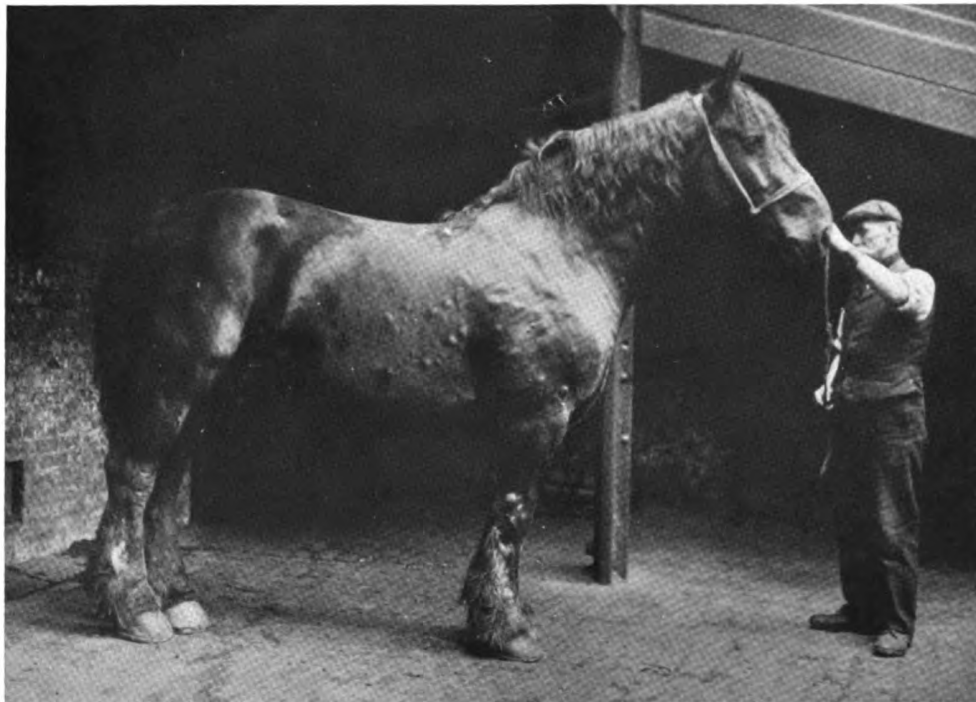

Turning to the cases of so-called rheumatic tendonitis, chiefly discussed that evening, he might say that that subject alone would have sufficed for a paper. At the previous meeting almost the last question asked was, What could be called rheumatism? The trend of the discussion appeared to define rheumatism as an intermittent lameness that could not be accounted for. If that were rheumatism, all must admit, as he believed, that rheumatism in the horse did exist; there were numerous cases of intermittent lameness (also metastatic) which could not be explained. He thought, however, that Mr. Eaglesham's cases hardly merited the term "rheumatic tendonitis." He had no doubt of the existence of a form of tendonitis that did

appear under the conditions described by Mr. Eaglesham; and there the speaker joined issue with Mr. Perryman, although he agreed with the latter's views in relation to some of the cases he had mentioned. The two sets of cases were not at all analogous—the conditions were entirely different. Certainly after some cases of influenza, strangles, or purpura, there was inflammation of the tendon sheaths which might become practically chronic, tending to the formation of fibrous tissues, which, contracting, caused knuckling, just as contraction of the fibrous tissue in a chronic strain would cause knuckling. This, however, should not be called rheumatic, as it had a definite specific origin, and was due to the same cause as the previous systemic affection, and in those special cases, an infection involved the tendon sheaths just as it might involve any other part of the body.

With regard to strained check ligament, the subject was not perhaps on the main theme, but he found himself in partial agreement with several speakers holding divergent views. He considered that Mr. Price's explanation of the thickening of the tendon following navicular disease merited some consideration, as did also Mr. Slocock's cases of strained check ligament following ringbones. In the speaker's opinion strain of the perforans tendon did occur as a secondary condition from some painful condition of the foot aggravated by concussion. In Mr. Price's case the animal would endeavour to correct the effects of concussion, caused by banging the foot down, by contracting his tendons, so in the case of ringbones. In each of those cases there would be a strain of the perforans tendon at the point of junction of the check ligament with the perforans tendon. In some cases fibrous thickening from a slight strain frequently repeated involved the check ligament, but the condition was not originally a strain of the check ligament, being a strain of the perforans tendon high up in the neighbourhood of the check ligament. He did not agree with Mr. Slocock's view that this condition did not cause lameness, the speaker believed that the condition did cause lameness, but in the case he referred to there were two co-existent causes. That applied to Mr. Martin's question as to whether it actually was the check ligament that was strained. He thought Mr. Martin had shown that the check ligament was hardly likely to be strained under such conditions, confirming the speaker's view that it was the perforans tendon at the junction of the check ligament that was strained. As to the question of rheumatism being due to organisms in the blood, raised at the last meeting, the whole problem was beset with difficulties. In the case recorded by Mr. Eaglesham, he thought it would be admitted that the lesions had been caused by organisms, and these organisms had been carried there by the blood stream; that should not be called rheumatism. In the speaker's opinion the term "rheumatism" should be limited to mean a painful condition of the fibrous structure of the body, either muscles, tendons, or ligaments, associated with deposition of salts in some of those structures. He thought it was due mainly to defects in the alimentary tract. He could quote chapter and verse for various cases in the human subject wherein those symptoms had invariably been secondary to alimentary trouble. In some forms of colitis in human beings the malady was attended by excruciating pains in various parts of the body. That being so, he usually considered that rheumatism should be treated with a smart purgative, such as calomel or aloes or a combination of both. In his opinion rheumatism was a toxæmia due to absorption of the toxin generated in the alimentary tract, which toxin being circulated in the blood and fibrous structures, became fixed there, causing myositis when involving the muscles, tendonitis in the case of tendons, and inflammation of the ligaments when the latter were involved. Local treatment in such cases

TENDONITIS.

MULTIPLE SARCOMA

Illustrating notes by Mr. R. EAGLESHAM, M.R.C.V.S.

was of secondary importance except as to relieving pain at the time, it did not remove the cause. He believed that Mr. Eaglesham's case was definitely due to metastasis of the organisms from the lungs or original seat of infection. He was quite convinced that tendonitis following on influenza did occur. On the other hand a considerable number of cases of strained and thickened tendons resulted from working horses in an unfit state. Both conditions might co-exist, differing, however, in origin and nature.

Mr. W. PERRYMAN did not wish it to be inferred from his previous remarks that he had never seen cases of effusion following pneumonia, pleurisy and purpura; he meant merely that it was incorrect to describe such cases as rheumatic. In the case of contraction mentioned by Mr. Eaglesham, he should be understood to have said that originally it was not rheumatism. His contention was that the majority of cases stated to be rheumatism were not such and were capable of other explanations. Capt. Rees-Mogg had referred to tubercles at the back of the pastern, but the speaker suggested ringbone might be the cause. To correct any misunderstanding on the part of Mr. Slocock he had not said that the trouble with the check ligament was rheumatic. In reference to the check ligament no speaker had mentioned the general thickening associated with splint lameness, particularly underneath the knee; if the lameness from the splint were got rid of, the lameness from the check ligament would disappear. [Mr. Slocock here observed that the acute metastatic lameness occurring with glanders was certainly not rheumatic.]

The PRESIDENT desired to reply to a question put at the last meeting: Were sarcomatous growths dangerous to the human being? An emphatic "no" was the answer. The Cancer Research Fund Experiments showed clearly that cancer was not inter-transmissible between different species; only transmissible from animal to animal of the same species. Cancer or sarcoma therefore was not transmissible from the horse, or other animal, to the human being.

Mr. R. EAGLESHAM then replied briefly to the discussion. His belief in bringing the cases forward was that they would be interesting to the clinical practitioner, and his object had been to hear the opinions of others. Cases of subcutaneous sarcomata in the horse were not numerous; in twenty-three years experience he had only met with two, the present case and one in a five-year-old horse. The sarcomata were not, he believed, very malignant; they were very slow in growth, and the horse would probably be worn out before they became unsightly. Mr. Thompson's case was one of the same class, and was very interesting. The rheumatic cases he had brought before the Fellows were chronic cases of infective origin. The cases he had come in contact with were mostly those met with in young horses, four to six years old. The animals had generally not done much work, and the trouble had followed bad illnesses during the convalescent stage.

Recently he had had a case of bursitis of a rheumatic type in a young horse, following purpura. The bursa affected was the sesamoidean of a front fetlock which became inflamed and painful, and caused troublesome lameness requiring treatment for six months to get it sound. Whether this class of case should be classified as rheumatism or not, he could not say, but he had known veterinarians of large clinical experience who had always classed them under that heading. He had met with cases of navicular bursitis in horses following pleurisy and dropsy of the chest which had rendered them more or less lame and unsound afterwards, and he had always classed these cases of lameness as of a rheumatic type. As he had said, the two cases he had described were six-year-old horses, which had not been

much worked, and he did not consider that in either case they had been put to work too early.

He thought that in the early stages iodide of potassium was the best treatment, followed by blisters, and a run "at grass." The renal case had lasted 2½ years. Since the last meeting, he had had the organs examined microscopically by Mr. Sheather at the Royal Veterinary College, and that gentleman had reported as follows:—

"I have examined the kidneys and bladder from the horse, which you brought here on Wednesday last. Microscopic examination shows that the kidneys were in a condition of interstitial nephritis. As is not infrequently the case, the lesion was not uniform in its distribution, areas of apparently quite normal kidney alternating with areas in which practically the whole of the uriniferous tubules were destroyed. The peculiar appearance presented by the pelvis of the kidneys was due to inflammatory changes induced, no doubt, by the presence of the renal calculi. Microscopic examination of the lesions present in the bladder showed that these were papillomatous in nature, and that the epithelium covering the outgrowths was the seat of an extensive round-celled infiltration. These lesions were, I think, due to the persistent irritant action of the sabulous deposit, which I gathered from you was present in the bladder. Dr. Lander kindly analysed one of the renal calculi for me, and he reports that it was composed practically entirely of carbonates."

The usual vote of thanks was passed to those who had exhibited specimens; and on the motion of Mr. Stroud, seconded by Mr. MacCormack, a hearty vote of thanks was passed to Mr. Eaglesham for the very interesting paper he had submitted.

HUGH A. MACCORMACK, Hon. Sec.

TENTH INTERNATIONAL VETERINARY CONGRESS, LONDON, Aug. 3—8, 1914.

GENERAL MEETINGS.

1. OFFICIAL OPENING MEETING
Monday Aug. 3, at 11 a.m.
2. FOOT-AND-MOUTH DISEASE
Tuesday, Aug. 4, at 10 a.m.
3. TUBERCULOSIS
Wednesday, Aug. 5, at 10 a.m.
4. EPIZOOTIC ABORTION
Thursday, Aug. 6, at 10 a.m.
5. PUBLIC CONTROL OF THE PRODUCTION, DISTRIBUTION AND SALE OF MILK IN THE INTERESTS OF PUBLIC HEALTH
Friday, Aug. 7, at 9 a.m.
6. DISINFECTION OF WAGGONS*
Friday, Aug. 7, at 12 noon.
7. OFFICIAL CLOSING MEETING
Saturday, Aug. 8, at 12 noon.

SECTIONAL MEETINGS.

Section I. VETERINARY SCIENCE IN RELATION TO PUBLIC HEALTH.

- (a) Meat Poisoning—its Pathogenesis and the measures necessary to guard against it
Tuesday, Aug. 4, at 2 p.m.
- (b) General principles to be observed in the inspection of carcasses and organs of Tuberculous Animals with a view to determine their safety as articles of Human Food
Wednesday, Aug. 5, at 2 p.m.
- (c) Construction and interior of stables in relation to the prophylaxis of diseases of animals, especially Tuberculosis, and also to the hygiene of milk [adjourned discussion]†
Thursday, Aug. 6, at 2 p.m.

* In accordance with Resolution of the IXth Congress. [1st. Section III., p. 9].

† Discussion adjourned from the IXth Congress. [Resolution of General Meeting XII].

Section II. PATHOLOGY AND BACTERIOLOGY.

- (a) John's Disease *Tuesday Aug. 4 at 2 p.m.*
 (b) Bovine Piropasmoses [European] *Wednesday, Aug. 5, at 2 p.m.*
 (c) Ultra-visible Viruses *Thursday, Aug. 6, at 2 p.m.*
 (d) Distemper [Etiology and Vaccination] *Friday, Aug. 7, at 2 p.m.*

Section III. EPIZOOTIOLOGY.

- (a) Anthrax *Tuesday, Aug. 4, at 2 p.m.*
 (b) Swine Fever *Wednesday, Aug. 5, at 2 p.m.*
 (c) Glanders *Thursday, Aug. 6, at 2 p.m.*
 (d) Sarcoptic Mange of the Horse *Friday, Aug. 7, at 2 p.m.*

Section IV. VETERINARY MEDICINE AND SURGERY.

- (a) Anæsthesia *Tuesday, Aug. 4, at 2 p.m.*
 (b) Laminitis *Wednesday, Aug. 5, at 2 p.m.*
 (c) Surgical Treatment of Roaring *Thursday, Aug. 6, at 2 p.m.*
 (d) The Use of Drugs in the Treatment of Disease caused by Nematode Worms *Friday, Aug. 7, at 2 p.m.*

Section V. TROPICAL DISEASES.

- (a) Diseases Transmitted by Ticks; their Classification, Treatment, and Prevention *Tuesday, Aug. 4, at 2 p.m.*
 (b) Diseases Transmitted by Winged Insects; their Classification, Treatment, and Prevention *Wednesday, Aug. 5, at 2 p.m.*

Section VI. ZOOTECHNY.

What influence has Heredity on the early development of affections which impair the economic usefulness of horses. What are the manifestations of these influences that should be avoided in the selection of breeding animals? * *Thursday, Aug. 6, at 3 p.m.*

*In accordance with Resolution of the IXth Congress (Fourth Section IV., p. 3).

PROGRAMME OF RECEPTIONS.

Sunday, August, 2nd:

RECEPTION BY THE ORGANISING COMMITTEE AND MEMBERS OF THE ROYAL COLLEGE OF VETERINARY SURGEONS, to be held at the Hotel Cecil, Strand, London, W.C., from 8.30 to 10.30 p.m.

Tuesday, August 4th:

CONVERSAZIONE GIVEN BY THE ORGANISING COMMITTEE AND MEMBERS OF THE ROYAL COLLEGE OF VETERINARY SURGEONS at the Natural History Museum, South Kensington, to Members of the Congress, from 9 to 11.30 p.m.

Wednesday, August 5th:

OFFICIAL DINNER OF THE CONGRESS, at the Hotel Cecil, Strand, W.C., at 7.30 p.m. Price of Tickets: Gentlemen £1 ls.; Lady 16 shillings, inclusive of wines and cigars.

It is hoped that members will attend the official dinner in large numbers. Those intending to be present should notify the Honorary Secretary not before Tuesday, July 28th, 1914.

Friday, August 7th:

MUNICIPAL RECEPTION TO MEMBERS OF CONGRESS.

Thursday, August 6th:

DINNER TO GOVERNMENT DELEGATES GIVEN BY HIS MAJESTY'S MINISTERS.

A SPECIAL ENTERTAINMENT FOR LADY MEMBERS IS BEING ARRANGED.

Notice as to Dress.

For morning and afternoon meetings: Gentlemen, Morning coat or frock; Ladies, Morning dress.

For all evening meetings, receptions, dinner, etc.: Gentlemen, Evening dress; Ladies, Evening dress.

It may be necessary to wear levée dress or uniform for Government or Municipal receptions. Instructions on this point will be given on the cards of invitation.

In order that there may be no mistake about invitations, members are requested to register their names at an early date as well as those of their ladies. Cards of invitation will be required for certain of the receptions, and members who have not received these are requested to apply for them at the Secretary's Office as soon as possible after their arrival in London.

The Office of the Secretary will be at the place of meeting during the Congress, The Central Hall, Westminster, and will be open all day on Saturday, August 1st, and from Monday, August 3rd, till Saturday, August 8th.

The City of London and the International Veterinary Congress.

The City Press says:—"The King has graciously accepted the post of Patron, and the President of the Board of Agriculture is acting as the President of the Council of Honour. On that Council all the Ambassadors and the Lord Mayor, who is the sole other member, are serving. Sir J. M'Fadyean is the Chairman of the Committee, and Sir Stewart Stockman, Chief Veterinary Officer for England, the Organising Secretary. The arrangements include an official reception and banquet by the Government. The Court of Common Council referred on Thursday to the Coal and Corn and Finance Committee for consideration a proposal to give a reception to the delegates at Guildhall. The project met with very sympathetic consideration, and the reference to Committee was hearty in the extreme.

Inspectors' Fees

A contributor sends us the following with a request for publication:

BOROUGH OF FOLKESTONE.**Duties of Veterinary Inspector.**

1. Generally to act as Veterinary Inspector under the Diseases of Animals Act, 1894, and any Act amending the same, and all orders made by the Board of Agriculture thereunder.
2. To act as Veterinary Inspector under the Tuberculosis Order of 1913.
3. To attend all public sales of swine in the Borough, to inspect all swine in trucks at the railway stations, and all swine and piggeries in the Borough.
4. To provide a place of detention for dogs as required by Article 2 of the Importation of Dogs Order of 1901.
5. To report to the Sanitary and Hospitals Committee once every quarter as to his inspection of swine and as to the work generally carried out by him during the preceding three months.
6. In respect of Nos. 3 and 5 of these duties the Corporation will pay a fixed fee of £10 per annum, in respect of No. 2, fees will be paid in accordance with the scale made by the Kent County Council on the 21st May, 1913, of "Fees and allowances payable to Veterinary Inspectors," and in respect of No. 1 fees will be paid for work done.
7. In respect of No. 4 of these duties, the Corporation will pay no fees, and the owner of the dog is the only person from whom payment can be claimed.
8. The appointment will be determinable by three calendar months' notice given by either party.

A. F. KIDSON, Town Clerk.

Folkestone, April 3rd, 1914.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, June 22, 1914
NOTE.—The figures for the Current Year are approximate only.

The Board of Agriculture and Fisheries have made Orders, under the Diseases of Animals Acts, 1894 to 1911, entitled, respectively, the Sheep Scab Order of 1914, and the Sheep (Double Dipping) Order of 1914, restricting the movement and requiring the double dipping of sheep on any premises or areas to which the provisions of the Orders are applied.

It is intended that these Orders shall be applied to particular premises or areas as and when considered necessary. The prevalence of sheep scab in Great Britain has been greatly reduced since 1907, when the compulsory dipping of sheep was first enforced throughout the country by Orders of the Board. It is hoped that by the enforcement of these more stringent Orders on particular premises, and in comparatively small areas, the complete eradication of the disease from Great Britain may be expedited.

The Board are at the same time taking additional precautions against the introduction of the disease into this country by sheep from Ireland.

June 9th.

The Board of Agriculture and Fisheries have been officially informed that the United States Government have resumed the issue of permits, for shipment on and after the 20th inst., for the importation into the United States of cattle, sheep and other ruminants, and swine from Great Britain.

The issue of such permits was suspended by the United States Government in consequence of the recent outbreaks of foot-and-mouth disease in this country.

All permits issued are subject to the approval of Dr. W. H. Wray, of "Maryland," Beaconsfield, Bucks, the representative of the United States Department of

Agriculture in Great Britain. Only hay, fodder, or litter forwarded from the United States, or such material originating from the farms from which the animals are shipped, or of known origin in Great Britain and approved by Dr. Wray will be allowed by the United States Government to accompany the animals, and the animals will not be permitted to be shipped on the same vessel with horses originating from the Continent of Europe. Horses from Great Britain can, however, be shipped on the same vessel as cattle, sheep, or other ruminants or swine from this country, subject to the origin of the fodder accompanying such horses being approved by Dr. Wray.

Board of Agriculture and Fisheries,
4 Whitehall Place,
London, S.W.

10th June, 1914.

PARLIAMENTARY.

In the House of Commons on Tuesday, June 16th.

THE POSITION OF AGRICULTURE.

The House went into Committee of Supply, Mr. MacLean (Peebles and Selkirk, Min.) in the Chair, on the Vote of £344,027 for the Board of Agriculture and Fisheries.

Mr. RUNCIMAN described the Estimate as the largest which the Board had ever had to present to Parliament. They were at present negotiating with the Argentine Government with a view to arriving at some arrangement which would enable English stockowners and

breeders in future to export cattle to the Argentine at a much earlier date than the present period of six months after the Board had declared this country to be free from disease. It was impossible for them to take any risks with regard to disease which might have originated in the Argentine and then find its way back to the United Kingdom, and it was on that basis that they had conducted their conversations with the representatives of the Argentine Government.

The position in Ireland had been far from reassuring, but they were still acting with great caution. Not a single case of infection had come into Great Britain because of the relaxations which they had granted. Thirty local authorities in England and 17 in Scotland had entirely prohibited Irish cattle in their boundaries. They were not going to be over-ridden by the Board, and he trusted they would take the advice of the Board that they would be acting quite safely if they were now to relax their prohibition. Any action taken must be absolutely prompt, and that could only be secured by leaving it in the hands of the executive officers and inspectors. It would be very little use saying they would not accept animals from one area in Ireland if the contacts were allowed to come in. The mere suspicion of disease in Ireland did more harm to the Irish farmers than the restrictions imposed by the Board.

THE PREVALENCE OF SWINE FEVER.

Foot-and-mouth disease had not involved them in losses anything like so large as those from swine fever, which during the last generation had been the most persistent and intractable of all animals' diseases. During the last few years they had not been able to diminish the area over which the disease was spread or to reduce seriously the number of outbreaks. The net expenditure on swine fever in the course of 12 months had been £120,000, spread over 2,900 outbreaks. They could not regard their present arrangements for dealing with the disease satisfactory. (Hear hear.)

COMMITTEE ON SWINE FEVER.

While good work could be done in the laboratory, arrangements had been made for experiments in the field as well. Experiments were to be conducted on 18 premises belonging to 10 owners in eight counties, and in one or two cases they would be conducted under such perfect conditions of isolation as, for instance, in the grounds of a large lunatic asylum, where great risks could be taken. (Laughter.) With the financial assistance of the Development Commission and with the help of representatives of outside bodies, arrangements had been made for concurrent research into this disease. Various preventive measures had been suggested—preventive inoculation, for example—with the object of getting rid of the present restrictions upon the movement of swine. But if inoculated animals were allowed to pass about freely, every stockowner would be compelled to adopt inoculation. That would prove just as costly to the big breeders as the present restrictions, and the Board could not therefore embark on a great change in that direction without the full concurrence of the stockowners. He recognised that the present restrictions were sometimes unnecessarily hurtful, because they depended upon artificial county boundaries, and if any county cared to approach the Board on the subject the Board would be prepared to go closely into their local conditions and, if possible, to relieve them of the disabilities under which they suffered. It was possible, also, that the scientific work of the next few years might enable the Board to take a bolder line with regard to swine fever.

TRAINING OF VETERINARY SCIENTISTS.

The supply of first-class veterinary scientists was by no means as large as it should be, and representations

had been made to the Treasury and the Development Commissioners in regard to the training of men. The Development Commissioners had, as an experiment, which he hoped would become a regular custom, agreed to the creation of two research scholarships in veterinary science of the annual value of £150, for a period of three years each, commencing in October next. In addition this year the Board would be offering three scholarships of £100 each, tenable for three years.

A NEW TUBERCULOSIS ORDER.

Dealing with the question of tuberculosis, Mr. Runciman said he hoped that the new Order would be issued at the beginning of July. It would provide for one valuation, which would be the market value of the cow at the time of the valuation. The new basis of compensation would be three-fourths of the value in non-advanced cases and one-fourth in advanced cases, with a minimum of 30s. in the latter cases. The refund to the local authorities would be three-fourths of the gross valuation, leaving with them also the right to the full salvage value. The Order would also provide that where an animal was held up for three days without the officer of the local authority coming to a decision on the subject it should be set free.

Mr. C. BATHURST moved to reduce the Vote by £100 in order to call attention to the Board's methods of combating swine fever, which consisted of the knife, the pole-axe, a meticulous network of harassing Government restrictions, and insufficient discrimination between serious and highly infectious disease such as foot-and-mouth disease and diseases of less importance such as swine fever. Their record in the matter was one of departmental ignorance and failure. In no country in Europe were the restrictions so harassing as those in this country, yet in no country in Europe had there been so continuous and progressive an increase in swine fever, and in none had their been so large a drop in the pig population. The restrictions were particularly hard on the small holder and the cottager. The agricultural community would no longer tolerate the existing Swine Fever Orders. Personally he thought too much emphasis was laid on the bacillus of the disease and not enough on the conditions in which it flourished. The pig was the cleanest of all domestic animals if only he were allowed to be so, yet he was treated as if he were the filthiest. Let the Board of Agriculture turn their minds to the pig-sty if they wished to get rid of the disease.

SIR J. SPEAR (Devon, Tavistock, Opp.) gave it as his opinion that the President of the Board had seriously failed to deal with the problem of swine fever. During the right hon. gentleman's tenure of office there had been an increase in the disease and in the number of animals slaughtered, and one of the consequences was a decrease of nearly 400,000 pigs in 1913, as compared with the preceding year. This, with the resulting high price of bacon, entailed great hardship on the consuming public, and especially on poor people. He suggested that, in dealing with swine fever, the Board should rely more than they did on the technical knowledge of the veterinary surgeons practising in the districts and less on the lay inspectors.

Mr. P. WHITE (Meath, N.) urged that there should be a Commission or Committee of Inquiry into the administration of the Diseases of Animals Act.

IRISH CATTLE.

Mr. T. W. RUSSELL (Tyrone, N.) stated that he could not undertake to open the ports in Ireland before he had received from the chief inspector an assurance that no danger would arise. When that was received there would be no difficulty in getting to business at once.

Mr. CRUMLEY (Fermanagh, S.) expressed disappointment that all restrictions were not to be relaxed immediately.

Serum Treatment for Swine Fever.

Writing to *The Farmers Gazette*, Dublin, Mr. John M. Harris, of the firm of Thos. Harris & Co., Ltd., says: "By the courtesy of Sir Stewart Stockman, Chief Veterinary Officer of the Board of Agriculture, I was permitted, a few days ago, to see and obtain particulars of the experiments which are being conducted by their Department at the laboratories at Alpertou and Hanwell.

1. At Alpertou I was shown two six-months-old pigs which were simultaneously inoculated four months ago with the swine fever virus and the remedial serum. They were ill for a few days thereafter. Six weeks ago a much stronger dose of the fever virus was administered to them and without the slightest ill-effects being manifested. The pigs are now strong and healthy.

2. Another pig, that was similarly dosed twelve months ago, had injected on the 5th May last what had hitherto been considered fatal doses of the fever virus. The pig is perfectly well at present.

3. On the 11th February last, fifteen pigs out of a pen of seventeen suffering from fever were inoculated with the serum, two of them being untreated. The untreated pigs died, whilst the fifteen which were subjected to the serum treatment are quite well and weigh 160 to 180 lb. carcase weight.

4. Six pigs out of another lot in a fever-infected sty were brought under the serum treatment and are doing well. Two pigs in this sty which were not so treated died as a consequence of the fever.

5. Twelve eight-weeks-old pigs were placed in a pen with a pig suffering badly from fever. All were subjected to the serum treatment on the 23rd April last. All are alive and doing well.

6. Nineteen small pigs were placed in a fever-infected pen, where they remained for five weeks, fifteen of them being treated with serum and four left untreated. All the four untreated pigs died and showed undoubted fever lesions, whilst the treated pigs are perfectly well and healthy.

7. Of four large old sows suffering from fever, two were inoculated with serum and are now perfectly well and being bred from. The other two sows in the pen which were untreated have died of fever.

8. Five sows in a fever-infected pen were treated with serum and have since farrowed and are alive and well."

The Zoological Society and the International Veterinary Congress.

The Zoological Society has presented Prof. Wooldridge with 1000 free tickets to the Zoo, available on the Sundays August 2nd and 9th, for the use of foreign visitors to the International Veterinary Congress. This is a compliment to the profession as a whole, and we understand that it is largely a personal compliment as well. Prof. Wooldridge and other members of the Camden Town staff have attended the Zoo animals regularly during recent years, and this comes in recognition of the good work they have done.

Royal Veterinary College Sports.

At Tufnell Park on Friday, June 12th, in beautiful weather, the Royal Veterinary College students held their annual sports. There was a fully representative company including Lady M'Fadyean, Mrs. E. S. Shave, Professors Macqueen, Shave, Wooldridge, Buckmaster, Lander, Marrett, Tinis, Reynolds, Messrs. R. Daubney, T. S. Price, B. Gorton, A. A. Pryer, V. Hare, and T. C. Wight.

The sports officials were:—Judges, Messrs. W. M. Barnard, E. G. D. Ratcliff (Blackheath Harriers), assist-

ed by Sir John M'Fadyean and Prof. Wooldridge; Prof. E. Brayley Reynolds officiated as starter, and Mr. R. F. C. Yorke, of the L.A.C., was timekeeper. Mr. R. H. Stalker, the hon. secretary, and the members of the Committee are to be congratulated upon the complete success of the afternoon. The prizes were distributed at the close by Mrs. Lander. During the afternoon the Prince of Wales Military Band, under Conductor Fredk. Skepelhorn (late 4th R.I. Dragoon Guards), gave a selection of music.

While many of the events were close, only one college record was broken, L. G. Housden, in the mile walk, beating M. F. Richardson's record in 1910 of 9min. 24sec. Housden's time being 8min. 26 3-5th sec.

100 Yds. Scratch Race.—Heat 1: H. Neave, 1; H. C. Driver, 2; Heat 2: F. L. Haydon, 1; J. Barlow, 2; Heat 3: E. C. Bowes, 1; E. W. Garry, 2; Heat 4, R. H. Stalker walk over. Final: R. H. Stalker, 1; F. L. Haydon, 2. Won by a foot. Time, 10 4-5th sec.

Putting the Weight.—R. H. Stalker, 30 ft. 5 in.

Throwing the Cricket Ball.—R. H. Stalker, 1 (99 yds. 7ft.); S. C. J. Bennett, 2 (93 yds. 5ft.); K. Simpson, 3 (77 yds. 7ft.).

220 Yds. Handicap.—Final: E. C. Bowes (6 yards start), 1; E. W. Garry (4), 2.

Long Jump.—H. Neave, 1 (18ft. 11 1/2 in.); L. G. Housden, 2 (18ft. 5 1/2 in.); E. C. Bowes, 3 (18ft. 2 1/2 in.).

120 Yds. Hurdle.—Heat 1, A. Drew, 2; Heat 2, C. K. Calder; Heat 3, P. F. Woodland. Final: P. H. Woodland, 1; C. K. Calder, 2. Time, 21 4-5th sec.

Sack Race: H. Chown, 1; L. Pugh, 2; A. Gibson, 3. High Jump.—J. E. Barnes, 1 (5ft. 11 in.); F. L. Haydon, 2 (4ft. 11 in.).

Mile Walk.—L. G. Housden, 1; G. H. Bennett, 2; L. P. Church, 3. Winner's time, 8min. 26 3-5th sec., which beats college record of 9min. 24sec.

Half-Mile Scratch.—L. G. Housden, 1; W. A. Dickinson, 2; A. Drew, 3. Time, 2min 20 sec.

Obstacle Race.—H. Chown.

Quarter-Mile Scratch.—H. Neave, 1; J. E. Barnes, 2; H. C. Driver, 3. Won easily. Time, 56 3-5th sec.

Mile Handicap.—L. G. Housden (scratch), 1; C. K. Calder (120 yds. start), 2; W. A. Dickinson (80), 3. Won by 120 yards. Time, 5min. 3-5th sec.

Several minor events added to the interest of the day, the College "Derby" of five furlongs on donkeys causing rare fun. The ladies had a race, as did the staff.

ARMY VETERINARY SERVICE.**THE ARMY VETERINARY CORPS.**

The Regimental Dinner was held at the Hotel Metropole, on Friday, June 19. Present:—

Maj.-General R. Pringle, C.B., D.S.O.

Colonels E. R. C. Butler, Sir F. Duck, K.C.B., K. Lees, J. Moore, A. E. Queripel, C. Rutherford, C.B., C.M.G., W. B. Walters, C.B.

Lieut.-Colonels A. E. Clarke, E. W. Larnder, W. A. McDougall, J. Reilly, R. Rowe, E. Taylor, W. R. Walker, H. T. Sawyer.

Majors E. B. Bartlett, G. Conder, W. B. Edwards, G. C. O. Fowler, J. J. Griffith, E. J. Lawson, E. E. Martin, A. G. Todd, G. M. Williams, F. W. Wilson.

Vet.-Major W. A. Pallin.

Captains E. P. Argyle, T. E. Burridge, W. J. Dale, L. L. Dixon, O. S. Fisher, H. E. Gibbs, A. Hodgkins, A. S. Lawrie, V. C. Leckie, T. Lishman, W. I. Macaulay, K. McL. McKenzie, R. W. Mellard, H. S. Mosley, J. S. Nimmo, F. C. O'Rorke, L. M. Verney, E. J. Wadley, H. C. Welch.

Lieutenants C. Davenport, J. R. Ellison, J. Smith, C. M. Stewart, G. Williamson, T. J. Davis.

Lieut. & Quartermaster T. E. Campey.

V. V. B. FUND—LONDON ORPHAN ASYLUM.

Through your courtesy may I inform the workers on behalf of Hilda Tait that she was duly elected to-day to the London Orphan Asylum, being 5th on the list of successful candidates. May I take this opportunity of thanking the many helpers in the profession who have secured this girl's election.

Only the hard work they have put into canvassing for this election could have secured these results.—Faithfully yours,

Southtown, Gt. Yarmouth.
June 22nd.

WM. SHIPLEY.

Personal.

Mr. J. MALCOLM ARMFIELD sails from Southampton in the Union Castle R.M.S. "Saxon," on the 27th inst., to take up duty on the Veterinary Staff of the British East Africa Company, at Livingstone, N. Rhodesia.

OBITUARY

FREDERICK JARVIS, M.R.C.V.S., Wimbledon.

Graduated, Lond: Dec., 1859.

Mr. Jarvis deceased on Thursday, 18th inst., from bronchitis, at the age of 81. He formerly practised in South Kensington, but retired in 1902. For a few years he resided at Bushey, Herts, and subsequently at Wimbledon.

VETERINARY RESEARCH.

Sir,

My attention has been called to your correspondence on the above subject especially in connection with the meeting of the Berks and Oxon Chamber of Agriculture which took place at Reading, and as there seems to be some misconception about it, perhaps you will allow me the privilege, seeing I was present, of stating a few facts with regard to it.

Although nominally an agricultural meeting it was certainly not a representative one as the medical men almost outnumbered the few farmers present. The majority obtained in favour of the resolution was only three, seven voting for it and four against.

The President was the mover of the resolution, and his friends were in full force, in fact it was a carefully organised attempt on the part of our leading medical pathologists to initiate a campaign with the ultimate object of obtaining control of veterinary research in this country.

The question of swine fever was only of secondary importance, and full use was made of the agitation against the regulations now in force. The arguments so ably put forward by Sir John M'Fadyean were almost unanswered.

Some of your correspondents suggest that those opposing the resolution wished to make a corner in veterinary research. May I say that during the whole discussion there was never a suggestion of such a thing. All broad-minded men will welcome any increase in knowledge which may be of benefit to agriculture and veterinary science, but, as a well-known farmer asked at the meeting—which, by the way, was not reported in the short *resumé* published in *The Times*—Why are medical men now so anxious to investigate animal diseases? Is it because of the funds which may in the near future be voted by Government for this purpose? This seems to me the whole pith of the matter. If there are only limited funds to be allotted to veterinary research are these to be given to Cambridge or some other University when our own schools are starving?

Although it was contended that Cambridge needed money yet the position of most of our veterinary colleges and research laboratories were ignored. It is lamentable that in a country where cattle are so valuable so little support is given to our institutions, and yet in spite of it they have done splendid work which compares most favourably with

work done in other places much more fully equipped. All our Colleges should have sufficient funds to properly equip their laboratories and to provide a larger staff of lecturers, so that those conducting research may have more time to devote to the work. Students could then be trained in laboratory technique, and if scholarships were given, as in every other branch of science, there would be plenty of men come forward to be trained as expert bacteriologists.

If I had thought that £1,000 placed in the hands of medical men would yield better results for agriculture than the same amount awarded to veterinarians I should not have voted against the resolution; but I am convinced, as are most of the leading agriculturists who have had experience, that the veterinary surgeon is the right man to advise on animal diseases.

Sir Clifford Allbutt, speaking of swine fever, says "the farmer, the veterinarian and the Government have had more than 30 years in which to contemplate this scourge, and with no better result than perpetual quarantine and slaughter," and goes on to say that the only way to put this right is to refer it to university research (not veterinary of course) and claims that it is only here—in a university—that one gets the proper "atmosphere" for scientific knowledge. Although disclaiming the intention of advertising any particular university, yet he states with delightful naïveté, that they have the proper accommodation at Cambridge for this work. It is significant that although there is usually such jealousy between the different universities, yet on this occasion representatives of Oxford, Cambridge and London Universities, also the Lister Institute, all combined and used their collective influence to obtain a favourable vote on the question.

We should expect support from our sister profession, and it is most disappointing to notice the antagonism shown. We might with equal fairness suggest, and I pointed this out at the meeting, that because, for example, cancer investigation has not yet resulted in any diminution of the disease and no cure has been obtained, it should be placed in the hands of veterinarians and we should be given the funds for the purpose. After listening to the learned professors one would think that all the diseases that human beings suffer from had been investigated and there was no more work to do. I might remind them that it is only within the last few years that any real advance has been made with the treatment of venereal diseases, and we are not so able to control or prevent them as Moses was in the case of the Children of Israel. Such common diseases as measles, scarlet fever, influenza and a dozen others all need investigating. It is another instance of "the mote in one's brother's eye and the beam in one's own."

I must apologise for the length of this letter, but I feel very strongly that unless we take our stand as a scientific profession and show more *esprit de corps* we shall be ousted from the position we are justly entitled to.—Yours faithfully,

GEO. P. MALE.

COLONIAL APPOINTMENTS.

Sir,

I note in *The Record* of April 25th, "S. Africa" complains of the small salary the Colonial Office gives to veterinary surgeons, yet he says he is married and lives on £500 a year. He must be a lucky man. Here a G.V.S., unmarried, cannot live on £450.

It is high time the salaries of these appointments were increased, for it is only misery to those who accept them.

When a man in England obtains a billet for £400 a year he thinks he will be able "to have a good time." But, alas, when he comes out to the Colonies he finds the cost of living at least three times as much as it is at home, and with only this small amount he is always in debt.

Before the applicant is given a colonial billet he must sign an agreement that he will hold the post for at least three years, no private practice being allowed. At the end of three years one has forgotten all one knew, so all hope of practising again at home has vanished, and the only way of earning any money is by retaining this post.

After three years one is put on the "permanent list"; with this privilege one has to pay 4 per cent. of one's

salary towards the widows and orphans fund—this means that we have to pay for the up-keep of other men's wives and children, as we cannot draw sufficient pay to get married ourselves. One does not come out to the tropics for the benefit of one's health, but one expects to get enough money to pay one's way. A man who has saved enough money at the end of four years to pay his passage home should consider himself very lucky.

The idea of having a pension may draw some people, but they should remember that they cannot draw this pension until they are 55. How many years is a man going to live after being in the tropics for twenty-five or thirty years?

These salaries would be increased if the profession would unite and boycott the Government until they offer a reasonable salary.

In the last *Record* (April 25th) there are only three men looking for billets, all the other advertisements are for men wanted to fill vacancies. This shows that there are plenty of billets to be obtained at home without going to the Colonies.

For those who wish to make money or want to get married, let experience teach them that they cannot do either out here with the salaries now offered. No salary should start at less than £500, and this to increase yearly by £20 to at least £750, not including allowances.

We expect to obtain some interest on the money and time spent at College, but assistants in firms, men who have paid nothing for their professional education draw about the same amount as we do on arrival, and can rise to partnerships and high salaries. They are given a first class passage home and out, and full pay when on leave. We are given a second class passage (the same as police inspectors) when we first come out, after that we have to find our own passage money.—Yours truly,

"ONE WHO HAS BEEN HAD."

[The following were unavoidably held over last week.]

NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

Sir,

In again asking for a small space in your columns it is not with the intention of prolonging a controversy calculated to weaken rather than strengthen the unity of our profession. In answering Mr. Spencer's letter I thought I had made it plain to any logical mind that the latter is my main object. It is to be regretted Mr. Spencer cannot see any difference between what "might have been said" and what was left "unsaid," this I attribute to his habit of reading and quoting parts of a sentence only. Jumping to conclusions on such weak premises is risky, generally erroneous and illogical, as it is in this case.

"Tact" could have suggested a wiser course to Mr. Spencer, viz., proof that the Society was still alive and opinions to the contrary premature by the immediate circulation of the long promised pamphlet whose non-appearance was apologised for some six months ago when the belated scale of fees was circulated, as it is he is thinning his own ranks.

However absurd as it may appear to Mr. Spencer, the fact remains that the publication of his scale of fees in *The Veterinary Record* levelled down our fees in Kent, not only for tubercular testing, but also for mallein testing and valuations, more than 33 per cent., absolute proof of which can be produced.—Yours very faithfully,

THO. C. TOOPER.

REDWATER IN CATTLE.

Sir,

Perhaps you might think it worth while giving space to enclosed cutting lest there may be some sleepy M.R.C.V.S. still unacquainted with the redwater subject.

The ignorant herds and wide awake druggists have reason to feel indebted to Mr. Ebbitt for spreading the light, and will boast of having discovered a nostrum for the destruction of the tick after they have read *The Irish Independent*.—Yours truly,

CORRESPONDENT.

"REDWATER IN CATTLE."

Sir,—The winter was mild, the ticks lived through it, and there is a scourge of redwater on lands that harbour the ticks. Every herd and local druggist have their own 'sure cure.' It does not often prove fatal (except in cows milking) if a saline purge is given at the commencement. The ignorance that prevails about its origin is shocking, especially in a live stock country like Ireland. I do not know who is to blame for such beliefs as they have.

The tick should be considered a disgrace and not a misfortune, when seen on cattle. Co. Meath has quite a number of cases, and I suppose other grass lands are affected. Under a Home Rule Parliament it should be weeded out of the country, for I know it can be done.

R. EBBITT, M.R.C.V.S.

Oldcastle, Co. Meath, June 6th, 1914."

Veterinary Societies—Addresses.

BORDER COUNTIES V.M.S.
